Foreword

The International Organisation of Legal Metrology (OIML) is a worldwide, intergovernmental organisation whose primary aim is to harmonise the regulations and metrological controls applied by the national metrological services, or related organisations, of its Member States. The main categories of OIML publications are:

- **International Recommendations (OIML R),** which are model regulations that establish the metrological characteristics required of certain measuring instruments and which specify methods and equipment for checking their conformity. OIML Member States shall implement these Recommendations to the greatest possible extent;
- **International Documents (OIML D),** which are informative in nature and which are intended to harmonise and improve work in the field of legal metrology;
- **International Guides (OIML G),** which are also informative in nature and which are intended to give guidelines for the application of certain requirements to legal metrology;
- **International Basic Publications (OIML B),** which define the operating rules of the various OIML structures and systems; and

OIML Draft Recommendations, Documents and Guides are developed by Project Groups linked to Technical Committees or Subcommittees which comprise representatives from OIML Member States. Certain international and regional institutions also participate on a consultation basis. Cooperative agreements have been established between the OIML and certain institutions, such as ISO and the IEC, with the objective of avoiding contradictory requirements. Consequently, manufacturers and users of measuring instruments, test laboratories, etc. may simultaneously apply OIML publications and those of other institutions.

International Recommendations, Documents, Guides and Basic Publications are published in English (E) and translated into French (F) and are subject to periodic revision.

Additionally, the OIML publishes or participates in the publication of **Vocabularies (OIML V)** and periodically commissions legal metrology experts to write **Expert Reports (OIML E)**. Expert Reports are intended to provide information and advice, and are written solely from the viewpoint of their author, without the involvement of a Technical Committee or Subcommittee, nor that of the CIML. Thus, they do not necessarily represent the views of the OIML.

This publication – reference OIML D 5, edition xxxx (E) – was developed by the OIML Technical Committee TC 4 *Measurement standards and calibration and verification devices*. It was approved for final publication by the International Committee of Legal Metrology at its xx meeting in xxxxxx 20xx and will be submitted to the International Conference on Legal Metrology in 20xx for formal sanction.

OIML Publications may be downloaded from the OIML web site in the form of PDF files. Additional information on OIML Publications may be obtained from the Organisation's headquarters:

1 Introduction

1.1 The discipline and function of metrology in general, and legal metrology particularly, have changed significantly over the last 20 years, both at national and international levels. Metrology is facing multiple developments such as the globalisation of economics and international trade, digitalisation ~~of~~, geopolitical changes, elimination of technical barriers to trade, liberalisation, privatisation and ~~redefinition of the role of metrology~~manufacturing.

Metrology ~~also~~ evolves together with implementation of quality management systems in various organisations, accreditation of testing and calibration laboratories, and conformity assessment procedures based on ~~the~~ production quality ~~systems~~systems. The quality of products and services is increasingly dependent on reliable measurements.

Metrology plays a key role in the adoption of scientific and technological innovations, the design and efficient manufacture of products that comply with the needs of the marketplace, and the detection and avoidance of non-conformities. It also provides the basis for fair trading in a domestic economy and international trading in the global market place.

Internal markets as well as the globalization of trade, industry and society require comparability of calibration, measurement and test results through traceability to the International System of Units (SI), which represents the coherent and long-term stable fixed anchor points in measurement.

1.2 In legal metrology, measurements are important for conformity assessment~~, specifically in legal metrology, which is based on requirements for~~ in the legal control of measuring instruments. Metrological traceability enters into legal metrology as a part of conformity assessment. The results of measurements covered by regulations shall be expressed in legal units and shall be traceable to the SI [9].

The importance attached to measurements is also reflected in relevant international measurement standards by the requirement that measurement results shall be traceable to the SI through national ~~realizations~~realisations in National Metrology Institutes (NMI) which can be referred to as national or international measurement standards. So, for example, according to ISO/IEC 17025:2017 [1], when the measurement accuracy and measurement uncertainty affect the validity of the reported result, or metrological traceability is a requirement, a measuring ~~equipment~~instrument shall be calibrated before being placed into service. The calibration program for ~~equipment~~measuring instrument shall ensure that all results obtained by the laboratory are metrologically traceable to SI units.

In line with another standard, ISO 9001:2015 [8], when traceability of measurement result ~~traceability~~ is a requirement, or the traceability is considered by the organisation to be an essential part of providing confidence in the validity of measurement results, a measuring ~~equipment~~instrument shall be calibrated or verified at specified intervals or prior to use, against measurement standards having the values that are traceable to ~~values for~~ international or national measurement standards.

1.3 Metrological traceability is based ~~in part~~ on demonstrated equivalence among national measurement standards, as stated in joint BIPM, OIML, ILAC and ISO declarations on the relevance of Mutual Recognition Arrangements (MRAs) [6] and on metrological traceability [7].

1.4 ~~This~~The traceability of measurement results is essential ~~if~~in order that the results of the ~~measurements~~measurement and the ~~claim on the applicable~~claimed measurement uncertainty are ~~to be~~ comparable and meaningful. National measurement systems provide the framework within which all associated values necessary for the proper performance of ~~a~~ calibration, testing or

verification are traceable to the SI or, if this is not possible, to the values ~~for~~of nationally or internationally agreed reference materials.

1.5 The quest for improved measurement quality is the main reason for the existence of hierarchy schemes. While the quality is achievable in a number of ways, the classical scheme based on a direct calibration chain is widely used and accepted.

1.6 In legal metrology, special precaution must be taken for a complete estimation of the measurement uncertainty to ensure the traceability of the measurement ~~values~~results. Verification is sometimes conducted without the explicitly corresponding measurement uncertainty estimation. In that cases, the MPE of the measuring instrument is specified taking into account the measurement uncertainty. Where verification is performed without any explicit or implicit consideration of the measurement uncertainty, then it may not be considered to preserve or assure traceability. Refer to OIML G 19 [11] for consideration of measurement uncertainty in legal metrology.

2 Scope

2.1 This Document ~~deals with the~~provides some key principles and methods of metrological traceability. It proposes general rules for the establishment of hierarchy schemes for measuring instruments including specification of calibration chains and methods for the dissemination of units. ~~The~~These schemes then serve as evidence of the metrological traceability.

2.2 This Document provides guidance and assistance to organisations on how to comply with the metrological traceability requirements for relevant standards. It is primarily intended ~~for~~to be used by legal metrology laboratories where supervision of measuring instruments and test equipment is an important ~~part~~element of quality assurance. ~~It~~This Document may also be used by organisations involved in industrial production processes (development, manufacture, installation, final inspection) and by calibration and testing laboratories.

2.3 Depending on the circumstances, ~~other ways~~methods of achieving metrological traceability other than those described herein may be applicable. ~~These~~While these other methods are not discussed in this Document, ~~but~~they may be described in other International Documents.

3 Terminology

Unless otherwise stated in the following sub-clauses, the terminology used in this Document conforms to the VIML [3], the VIM [2] and the GUM [4].

For the purpose of this Document, the definitions and abbreviations given below apply.

3.1 International System of Units
SI (VIM, 1.16)
system of units, based on the International System of Quantities, their names and symbols, including a series of prefixes and their names and symbols, together with rules for their use, adopted by the General Conference on Weights and Measures (CGPM)

For notes see (VIM, 1.16).

3.2 metrology (VIM, 2.2)
science of measurement and its application

Note: Metrology includes all theoretical and practical aspects of measurement, whatever the measurement uncertainty and field of application.

3.3 measurement uncertainty (VIM, 2.26)
uncertainty of measurement
uncertainty
non-negative parameter characterising the dispersion of the quantity values being attributed to a measurand, based on the information used

Note 1: Measurement uncertainty includes components arising from systematic effects, such as components associated with corrections and the assigned quantity values of measurement standards, as well as the definitional uncertainty. Sometimes estimated systematic effects are not corrected for but, instead, associated measurement uncertainty components are incorporated.

Note 2: The parameter may be, for example, a standard deviation called standard measurement uncertainty (or a specified multiple of it), or the half-width of an interval, having a stated coverage probability.

Note 3: Measurement uncertainty comprises, in general, many components. Some of these may be evaluated by Type A evaluation of measurement uncertainty from the statistical distribution of the quantity values from series of measurements and can be characterised by standard deviations. The other components, which may be evaluated by Type B evaluation of measurement uncertainty, can also be characterized by standard deviations, evaluated from probability density functions based on experience or other information.

Note 4: In general, for a given set of information, it is understood that the measurement uncertainty is associated with a stated quantity value attributed to the measurand. A modification of this value results in a modification of the associated uncertainty.

3.4 expanded measurement uncertainty (VIM, 2.35)
expanded uncertainty
product of a combined standard measurement uncertainty and a factor larger than the number one

Note 1: The factor depends upon the type of probability distribution of the output quantity in a measurement model and on the selected coverage probability.

Note 2: The term "factor" in this definition refers to a coverage factor.

Note 3: Expanded measurement uncertainty is termed "overall uncertainty" in paragraph 5 of Recommendation INC-1 (1980) (see the GUM) and simply "uncertainty" in IEC documents.

~~3.4~~3.5 **calibration** (VIM, 2.39)
operation that, under specified conditions, in a first step, establishes a relation between the quantity values with measurement uncertainties provided by measurement standards and corresponding indications with associated measurement uncertainties and, in a second step, uses this information to establish a relation for obtaining a measurement result from an indication

For notes see (VIM, 2.39).

~~3.5~~3.6 **calibration hierarchy** (VIM, 2.40)
sequence of calibrations from a reference to the final measuring system, where the outcome of each calibration depends on the outcome of the previous calibration

For notes see (VIM, 2.40).

~~3.6~~3.7 **metrological traceability** (VIM, 2.41)

property of a measurement result whereby the result can be related to a reference through a documented unbroken chain of calibrations, each contributing to the measurement uncertainty

Note 1: For this definition, a 'reference' can be a definition of a measurement unit through its practical ~~realization~~realisation, or a measurement procedure including the measurement unit for a non-ordinal quantity, or a measurement standard.

Note 2: Metrological traceability requires an established calibration hierarchy.

For other notes see (VIM, 2.41).

~~3.7~~3.8 metrological traceability chain, traceability chain (VIM, 2.42)
sequence of measurement standards and calibrations that is used to relate a measurement result to a reference

Note 1: A metrological traceability chain is defined through a calibration hierarchy.

Note 2: A metrological traceability chain is used to establish metrological traceability of a measurement result.

Note 3: A comparison between two measurement standards may be viewed as a calibration if the comparison is used to check and, if necessary, correct the quantity value and measurement uncertainty attributed to one of the measurement standards.

~~3.8~~3.9 metrological traceability to a measurement unit, metrological traceability to a unit (VIM, 2.43)
metrological traceability where the reference is the definition of a measurement unit through its practical realisation

Note: The expression "traceability to the SI" means 'metrological traceability to a measurement unit of the International System of Units'.

3.10 verification (VIM, 2.44)
provision of objective evidence that a given item fulfils specified requirements

Example 1: Confirmation that a given reference material as claimed is homogeneous for the quantity value and measurement procedure concerned, down to a measurement portion having a mass of 10 mg.

Example 2: Confirmation that performance properties or legal requirements of a measuring system are achieved.

Example 3: Confirmation that a target measurement uncertainty can be met.

Note 1: When applicable, measurement uncertainty should be taken into consideration.

Note 2: The item may be, e.g. a process, measurement procedure, material, compound, or measuring system.

Note 3: The specified requirements may be, e.g. that a manufacturer's specifications are met.

Note 4: Verification in legal metrology, as defined in VIML [3], and in conformity assessment in general, pertains to the examination and marking and/or issuing of a verification certificate for a measuring system.

Note 5: Verification should not be confused with calibration. Not every verification is a validation.

Note 6: In chemistry, verification of the identity of the entity involved, or of activity, requires a description of the structure or properties of that entity or activity.

~~3.9~~3.11 **measuring instrument** (VIM, 3.1)
device used for making measurements, alone or in conjunction with one or more supplementary devices

Note 1: A measuring instrument that can be used alone is a measuring system.

Note 2: A measuring instrument may be an indicating measuring instrument or a material measure.

~~3.10~~3.12 **measuring system** (VIM, 3.2)
set of one or more measuring instruments and often other devices, including any reagent and supply, assembled and adapted to give information used to generate measured quantity values within specified intervals for quantities of specified kinds

Note: A measuring system may consist of only one measuring instrument.

~~3.11~~3.13 **indicating measuring instrument** (VIM, 3.3)
measuring instrument providing an output signal carrying information about the value of the quantity being measured

Examples: Voltmeter, micrometer, thermometer, electronic balance.

Note 1: An indicating measuring instrument may provide a record of its indication.

Note 2: An output signal may be presented in visual or acoustic form. It may also be transmitted to one or more other devices.

~~3.12~~3.14 **material measure** (VIM, 3.6)
measuring instrument reproducing or supplying, in a permanent manner during its use, quantities of one or more given kinds, each with an assigned quantity value

Examples: Standard weight, volume measure (supplying one or several quantity values, with or without a quantity-value scale), standard electric resistor, line scale (ruler), gauge block, standard signal generator, certified reference material.

Note 1 The indication of a material measure is its assigned quantity value.

Note 2 A material measure can be a measurement standard.

~~3.13~~3.15 **measurement standard**
etalon (VIM, 5.1)
realisation of the definition of a given quantity, with stated quantity value and associated measurement uncertainty, used as a reference

For examples and notes see (VIM, 5.1).

~~3.14~~3.16 **national measurement standard**
national standard (VIM, 5.3)
measurement standard recognised by a national authority to serve in a state or economy as the basis for assigning quantity values to other measurement standards for the kind of quantity concerned

~~3.15~~3.17 **primary measurement standard**
primary standard (VIM, 5.4)
measurement standard established using a primary reference measurement procedure, or created as an artifact, chosen by convention

For examples see (VIM, 5.4).

~~3.16~~3.18 reference measurement standard
reference standard (VIM, 5.6)
measurement standard designated for the calibration of other measurement standards for quantities of a given kind in a given organisation or at a given location

~~3.17~~3.19 working measurement standard
working standard (VIM, 5.7)
measurement standard that is used routinely to calibrate or verify measuring instruments or measuring systems

Note 1: A working measurement standard is usually calibrated with respect to a reference measurement standard.

Note 2: In relation to verification, the terms "check standard" or "control standard" are also sometimes used.

~~3.18~~3.20 reference material
RM (VIM, 5.13)
material, sufficiently homogeneous and stable with reference to specified properties, which has been established to be fit for its intended use in measurement or in examination of nominal properties

For examples and notes see (VIM, 5.13).

~~3.19~~3.21 certified reference material
CRM (VIM, 5.14)
reference material, accompanied by documentation issued by an authoritative body and providing one or more specified property values with associated uncertainties and traceabilities, using valid procedures

For examples and notes see (VIM, 5.14).

~~3.20~~3.22 maximum permissible measurement error
maximum permissible error
limit of error (VIML, 0.05)
extreme value of measurement error, with respect to a known reference quantity value, permitted by specifications or regulations for a given measurement, measuring instrument, or measuring system

Note 1: Usually the term "maximum permissible errors" or "limits of error" are used, where there are two extreme values.

Note 2: The term "tolerance" should not be used to designate 'maximum permissible error'.

[OIML V2-200:2012, 4.26]

Note 3: Usually the term "maximum permissible error" is abbreviated to "MPE", or "mpe".

~~3.21~~3.23 legal metrology (VIML, 1.01)
practice and process of applying statutory and regulatory structure and enforcement to metrology

Note 1: The scope of legal metrology may be different from country to country.

Note 2: Legal metrology includes

- setting up legal requirements,
- control / conformity assessment of regulated products and regulated

activities,
- supervision of regulated products and of regulated activities, and
- providing the necessary infrastructure for the traceability of regulated measurements and measuring instruments to SI or national standards.

Note 3: There are also regulations outside the area of legal metrology pertaining to the accuracy and correctness of measurement methods.

3.24 legal metrological control (VIML, 2.01)
the whole of legal metrology activities

Note: Legal metrological control includes
- legal control of measuring instruments,
- metrological supervision,
- all the operations for the purpose of examining and demonstrating, e.g. to testify in a court of law, the condition of a measuring instrument and to determine its metrological properties, amongst others by reference to the relevant statutory requirements.

~~3.22~~3.25 legal control of measuring instruments (VIML, 2.02)
generic term used to globally designate legal operations to which measuring instruments may be subjected, e.g. type approval, verification, etc.

~~3.23~~3.26 type approval (VIML, 2.05)
decision of legal relevance, based on the review of the type evaluation report, that the type of a measuring instrument complies with the relevant statutory requirements and results in the issuance of the type approval certificate

Note: See also VIML, A.25.

~~3.24~~3.27 verification of a measuring instrument (VIML, 2.09)
conformity assessment procedure (other than type evaluation) which results in the affixing of a verification mark and/or issuing of a verification certificate

Note: See also OIML V2-200:2012, 2.44.

~~3.25~~3.28 hierarchy scheme
descriptive and graphical specification of metrological traceability chain for a given ~~kind~~type of measuring instrument which serves to evidence their metrological traceability

~~3.26~~3.29 national hierarchy scheme
hierarchy scheme for a given ~~kind~~type of measuring instrument in the particular country, containing the specification of the recommended (permissible) ~~kinds~~types of measuring instruments for individual levels of metrological traceability, requirements for their metrological characteristics (accuracy class, maximum permissible error, etc.) and recommended (permissible) methods and means of dissemination of units

~~3.27~~3.30 local hierarchy scheme
hierarchy scheme for a given ~~kind~~type of measuring instrument at a given location, in a given organisation or in a given laboratory, containing the specification of the reference and working measurement standards, their metrological characteristics and the methods and means of dissemination of units

~~3.28~~3.31 means of dissemination of units

technical devices, reference materials or material measures, which are necessary to carry out calibration by comparing the measurement standards and the measuring instruments to be calibrated

Note: These means influence uncertainties of dissemination of units.

~~3.29~~3.32 National Metrology Institute (Designated Institute)
institute in a country that has a responsibility, sometimes set out legally, for the conservation of one or more national measurement standards

Note 1: The recommended role of a National Metrology Institute (NMI) is described in detail in OIML D 1:2012, 3.2.3 [10].

Note 2: The recommended role of a Designated Institute (DI) is described in CIPM 2005-07 [14] and CIPM 2005-06 (V4) [15].

~~3.30~~3.33 legal metrology laboratory (legal metrology services)
laboratory of an authorised institute responsible for a legal control of measuring instruments, e.g. type approval, verification, etc.

Note 1: The recommended role of such an institute is described in detail in OIML D 1:2012, 3.2.2.3 [10].

Note 2: Legal metrology laboratories are generally laboratories of the state legal metrology services or private metrology laboratories charged (authorised) by the national (legal) metrology authority to carry out legal control of measuring instruments within a defined scope.

~~3.31~~3.34 accredited calibration laboratory
laboratory that performs calibration of measuring instruments and that is formally recognised by an accreditation authority and that is competent to carry out the calibration (e.g. competence in accordance with ISO/IEC 17025:2017 [1])

4 Metrological traceability and its elements

4.1 Objectives of metrological traceability

Metrological traceability of the results obtained through the use of measuring instruments or reference materials and test equipment by means of traceable calibration or verification is necessary to provide comparability of measurement results the benefits of which include:

a) to ~~meet~~support the requirements of growing national and international trade;
b) to guarantee the product quality and compatibility of manufactured parts;
c) to protect the interests of individuals and enterprises,
d) to protect national interests; and
e) to protect public health and safety, including the environment, medical and related services.

4.2 Application in legal metrology

~~**4.2.1 To provide the metrological traceability for the application of legal metrology control, the evaluation of the measurement uncertainty may be necessary.**~~

~~**4.3 Other legal applications**~~

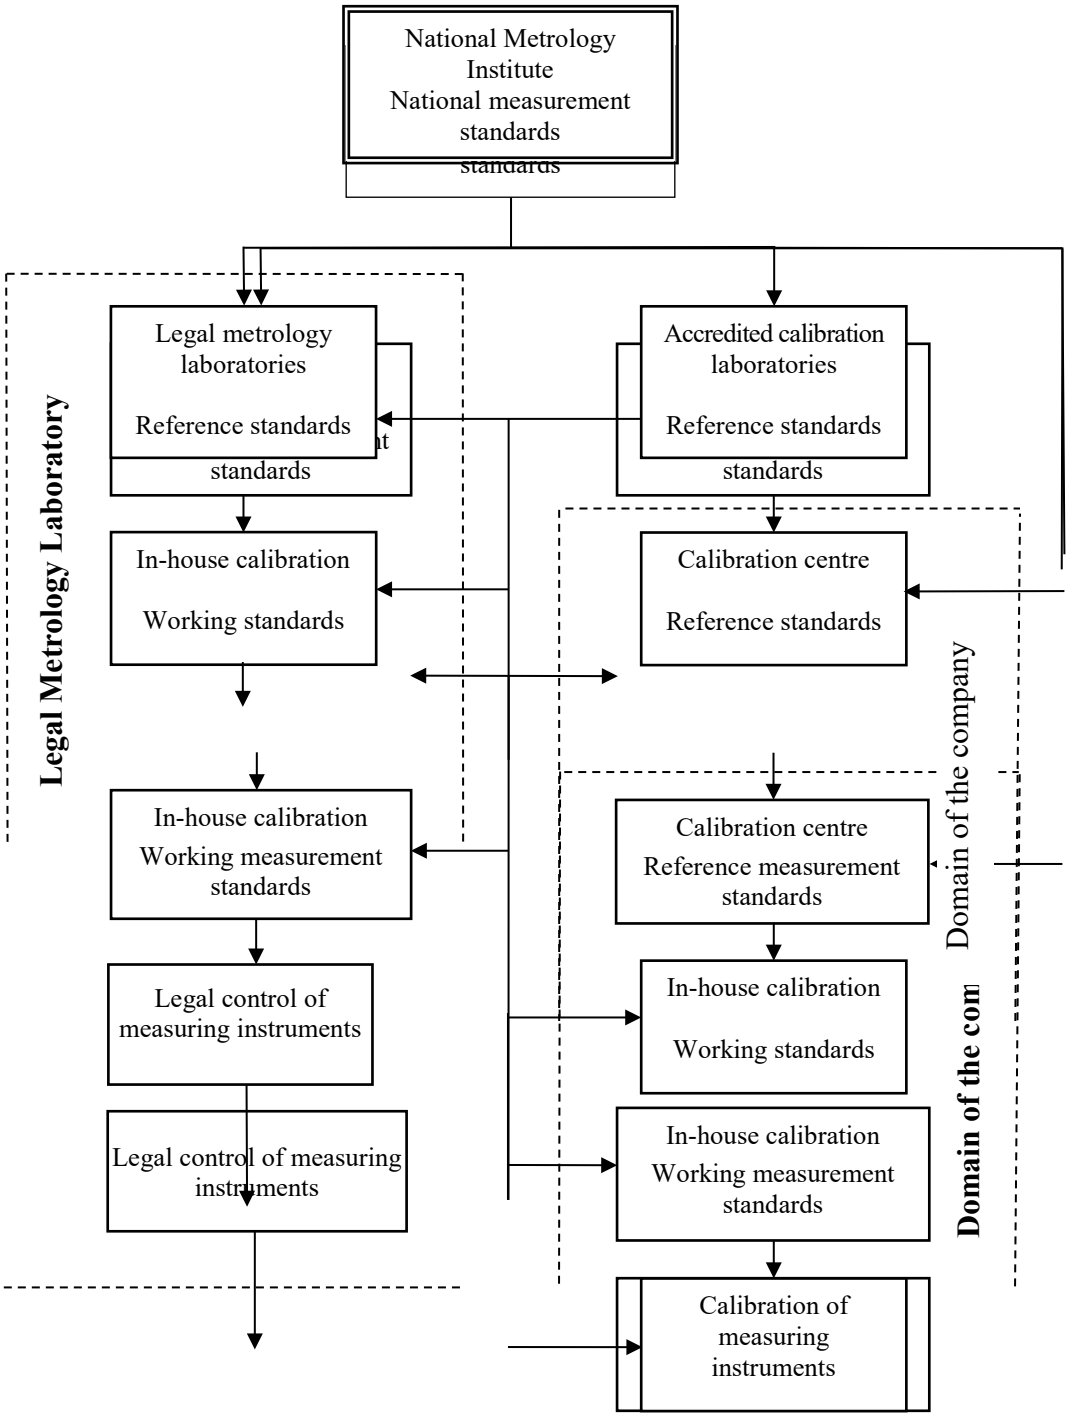
~~4.3.1~~4.2.1 For the application of any laws and regulations prescribing requirements on measurements, on prepackages and on measuring instruments, metrological traceability to SI units is required ~~and~~. The traceability may be obtained through the system of national

measurement standards and certified reference materials provided either by local sources or by any other internationally recognised sources.

4.2.2 The evaluation of the measurement uncertainty may be necessary to provide the metrological traceability for the application of legal metrology control.

4.44.3 Metrological traceability

~~The term "~~Metrological traceability~~" means~~ generally requires that ~~the indication of an indicating measuring instrument (or a material measure) has been~~measurement results are compared, in one or more stages, with the realisation of the SI for the measurand in question. In each of these stages, a calibration has been performed using a measurement standard for which the value and uncertainty have already been determined by calibration with a higher-level standard. Therefore there is a hierarchy of calibrations as shown in Fig. 1.



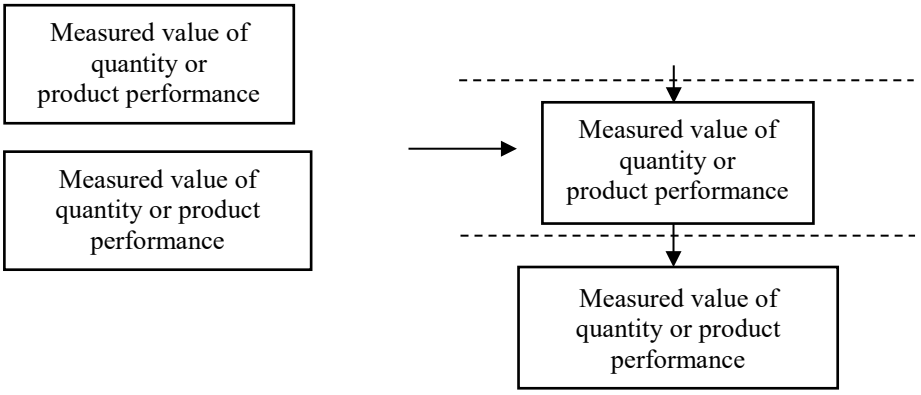


Fig. 1 Hierarchy of calibrations

The following essential elements are important to metrological traceability within the context of legal metrology:

a) Measurement uncertainty: the measurement uncertainty for each step in the metrological traceability chain shall be ~~calculated~~evaluated according to agreed methods, based on the GUM [4] and shall be stated in such a way that an overall uncertainty for each subsequent stage of the chain may be ~~calculated~~evaluated.

b) Documentation: each step in the chain shall be performed according to documented and generally acknowledged procedures; the results shall also be documented.

c) Competence~~;~~: the laboratories performing one or more steps in the chain shall supply evidence in support of their technical competence (equipment, skills of personnel, environmental conditions, etc.) and shall be accredited~~.~~ or peer assessed and/or their services are covered by the Mutual Recognition Arrangement of the International Committee of Weights and Measures (CIPM MRA) [18].

d) Specification of the measurand: the measurand that is subject of the hierarchy of calibrations.

~~d)~~e) Reference to SI units: the unbroken chain of calibrations shall end at primary standards for the realisation of the SI units or at measurement standards, against which metrological traceability to primary standard is demonstrable (as far as technically possible or applicable).

~~e)~~f) Recalibration: calibration shall be repeated at specified intervals depending upon a number of variables, e.g. uncertainty required, frequency of use, way of use, stability of ~~equipment~~measuring instruments and this information shall be stated in the documentation of the standard.

~~f)~~g) Initial verification: verification of a measuring instrument which has not been verified previously.

~~g)~~h) Subsequent verification: verification of a measuring instrument after a previous verification ~~carried out periodically at specified intervals~~ according to the ~~procedure laid down~~procedures specified by the regulations.

~~4.5~~4.4 Maximum permissible error

For practical reasons, especially for verifications in legal metrology or for the case of repeated standard ~~or,~~ routine calibrations or quality measurements, a maximum permissible error (MPE) of the measurement standard ~~(~~, reference material or measuring instrument~~) indications~~ is specified instead of the measurement uncertainty. In such a case, the MPE should be defined

taking into account the measurement uncertainty. ~~However,~~The compliance with the prescribed maximum permissible error alone should not necessarily be considered to ~~ensure traceability~~demonstrate traceability. With respect to the metrological traceability, the MPE of the measuring instrument shall be accompanied with information on the measurement uncertainty that relates to that MPE.

~~**4.6 Elements of metrological traceability**~~

4.5 Documentation

~~4.6.1~~**4.5.1** Reference and working measurement standards and means of dissemination of units have to be provided ~~by~~with documentation in accordance with the valid regulations.

~~4.6.2~~**4.5.2** The basic document for these measurement standards and means of dissemination of units is the valid calibration certificate issued either by an accredited calibration laboratory or by a laboratory demonstrating metrological traceability to the national measurement standard.

~~4.6.3~~**4.5.3** Other important parts of metrological traceability documentation are calibration or verification methods and procedures, which must clearly describe the metrological traceability of the measurement results. That is, the procedures have to clearly define which measurement standards and means of dissemination of units are used for the traceability. These procedures must also state the detailed procedure for evaluating measurement uncertainties ~~of calibrated~~in calibration or ~~verified~~verification of measuring instruments.

~~4.7~~4.6 Reference materials

In many fields, certified reference materials ~~play~~perform the role of reference and working measurement standards. It is equally important that ~~values assigned for~~the measurement results obtained by using such reference materials are traceable to relevant SI units realised by national or international measurement standards. Certification of reference materials is a method that is often used to demonstrate metrological traceability to national or international measurement standards.

Note 1: Additional information on the reference materials can be found in ISO 17034:2016 [16] or ISO Guide 35:2017 [17].

Note 2: Reference materials produced by ~~accredited~~ RMPs (Reference materials producers) as per ISO 17034:2016 [16] ~~are also~~may be considered as traceable to national or international standards~~.~~ if the ILAC policy for traceability provided through reference materials and certified reference materials is followed. Further information may be found in ILAC P10 [18].

5 Levels of dissemination of units of measurement

5.1 International level

At the international level, decisions concerning the International System of Units (SI) and the ~~realization~~realisation of the primary standards are taken by the ~~Conférence Générale des Poids et Mesures~~General Conference on Weights and Measures (CGPM). The ~~Bureau~~ International ~~des Poids et mesures~~Bureau of Weights and Measures (BIPM) is charged with coordinating the development and maintenance of the realisation of the units and organises key comparisons (intercomparisons on the highest level).

5.2 National Metrology Institutes (NMI)

5.2.1 The National Metrology Institutes are the highest authorities in metrology in almost all countries. NMIs represent the country internationally in relation to the NMIs of other countries,

the Regional Metrology Organisations and the BIPM. Some countries have a single authorised institute as their NMI, whereas others have a more distributed national metrological system (e.g. including one or more Designated Institutes).

5.2.2 In most cases the NMIs maintain the national measurement standards of the country that are the sources of metrological traceability for the associated physical quantities in that country. If the NMI has facilities and skills to realise the corresponding SI base units and derived units, the national measurement standards may be equivalent to the primary standards realising the units. If the NMI does not have this facility, it shall ensure that the measurement results are traceable to the SI through the standards maintained in another country, preferably to measurement standards realised at an NMI which is a signatory to the Mutual Recognition Arrangement of the ~~Comité~~ International ~~des Poids et Mesures~~Committee of Weights and Measures (CIPM MRA~~).~~) for the relevant quantity. If this condition is fulfilled, then the calibration certificates issued by this NMI are considered as internationally acceptable. The NMIs ensure that the realisation of the units themselves are internationally compared within the framework of the CIPM MRA. They are responsible for dissemination of the units of measurement to users, scientists, public authorities, laboratories or industrial enterprises and are therefore at the top level of the metrological infrastructure in a country.

5.2.3 Metrological traceability to the standards maintained by NMIs may be checked by reference to the Calibration and Measurement Capabilities (CMC) of NMIs held on the BIPM's key comparison database (KCDB) published on the BIPM web site (www.bipm.org).

5.3 Accredited calibration laboratories

5.3.1 Calibration laboratories accredited by ~~national~~ accreditation bodies according to internationally established criteria (e.g. ISO/IEC 17025:2017 [1]) shall be able to demonstrate that the measurement results associated with the calibration of measuring instruments ~~and measurement results is~~are traceable to SI units.

Note: Some calibration laboratories indicate that their service is covered by the ILAC Mutual Recognition Arrangement (ILAC MRA) by including the combined ILAC ~~Laboratory Combined~~ MRA mark on the calibration certificate. Alternatively, the accreditation ~~symbol~~mark of the accreditation body that is a signatory to the ILAC MRA ~~and/~~or ~~a recognised regional MLA~~the reference to its accreditation status may be included on the calibration certificate. Both of these options may be taken as evidence of traceability [18].

5.3.2 Accredited calibration laboratories are often at the top of a firm's internal calibration hierarchy. Their task is to compare, at appropriate intervals, the firm's own working measurement standards with reference measurement standards~~, which are~~ calibrated by an NMI or an accredited laboratory with suitable calibration and measurement capability.

5.3.3 Many accredited laboratories carry out calibrations for third parties, e.g. for organisations that are not equipped with calibration facilities and for private test laboratories as well, which work in the field of product certification. In this case the customer has to be assured that the measurement uncertainty achieved in a laboratory is suitable and sufficient for the intended use of the measuring instrument to be calibrated.

5.3.4 Accredited calibration laboratories generally documents the calibration results ~~are documented~~ in ~~a~~ calibration certificates.

5.4 Legal metrology laboratories

5.4.1 Legal metrology laboratories ~~should be able to demonstrate~~shall ensure that ~~the~~ measurement ~~standards values and measuring instruments values~~results used for verification ~~are traceable to the SI units~~ within their scope of authorisation according to ~~the~~ national legislation~~.~~ are traceable to the SI. Their reference measurement standards are calibrated by an NMI ~~or an accredited laboratory~~ with suitable Calibration and Measurement Capabilities or an accredited laboratory.

Note: Further guidance may be found in EN ISO/IEC 17025 [1] section 6.5.2.

5.4.2 Legal metrology laboratories or services in some countries are accredited according to a relevant international standard, e.g. according to ISO/IEC 17025:2017 [1], ISO/IEC 17020:2012 [12], or ISO/IEC 17065:2012 [13].

5.5 In-house calibration

5.5.1 In-house calibration means regular calibration of own working measurement standards~~, or~~ measuring ~~and test equipment used in a~~instruments which is performed by the metrology laboratory~~ or in a company against its own reference standards that are traceably calibrated at an~~, the accredited calibration laboratory~~, a legal metrology laboratory~~ or ~~an NMI~~the company itself against its own reference measurement standard with metrological traceability.

5.5.2 The scope of in-house calibration is at the discretion of the laboratory or company concerned. Even so, the results obtained using the measuring instruments and test equipment should be sufficiently accurate and reliable.

5.6 Hierarchy of measurement standards

The ~~hierarchy~~hierarchies of measurement standards and the responsible metrological organisations in ~~a~~each country~~, which ensures that all results of the tests and measurements~~ are ~~traceable to the SI is~~ shown in Fig. 2.

Measurement standard (measuring ~~equipment~~instrument)	**Responsibility**	**Tasks**	**Basis** for the legal metrological control, calibration or measurements	**Outputs** from the legal metrological control, calibration and measurements
 **National measurement standards**	National Metrology Institute (NMI)	To maintain National measurement standards and disseminate the measuring units and calibration of reference measurement standards or certification of reference materials	Statutory duty to represent SI units and ensure international comparability / CIPM MRA for national measurement standard	Calibration certificate for reference standard or reference material certificate
 **Reference measurement standards**	Legal metrology laboratories ~~and~~, accredited calibration laboratories and reference material producers	Calibration of working measurement standards or production of certified reference materials to safeguard the metrology infrastructure of country	Calibration certificate or reference material certificate from NMI or other accredited laboratory	Calibration certificate or reference material certificate for working measurement standard
 **Working measurement standards**	Legal metrology laboratories, accredited calibration laboratories and in-house calibration	Legal metrological control or calibration of ordinary measuring instruments	Calibration certificate or reference material certificate from NMI or legal metrology laboratory or accredited laboratory	Calibration or type approval or verification certificate. Type approval or verification or calibration mark
 **Ordinary instruments**	User	Measurement and tests performed by legally controlled or calibrated measuring instruments, or as a part of quality assurance measures	Verification or calibration certificate or verification or calibration mark of measuring instruments from legal metrology laboratory or accredited calibration laboratory or in-house calibration	Measurement and test results

~~for tracing measurement and test results~~

6 General principles for the establishment of hierarchy schemes for measuring instruments, their structure and practical realisation

A hierarchy scheme for measuring instruments is a graphically illustrated system of gradually arranged measuring instruments determining the unbroken chains of calibrations from the national measurement standard down to measuring instruments, giving methods of dissemination of units, important metrological characteristics and mutual links.

6.1 General principles for the establishment of hierarchy schemes

6.1.1 The hierarchy scheme may cover either the overall field of measurements of a particular quantity or only a defined part of it, which is characterised by one or more of the following specifications:

a) purpose (e.g. scientific metrology, verification in legal metrology, calibration, quality measurement etc.);
~~a)~~b) range of values of measured quantity (e.g. high temperatures, low absolute pressures etc.);
~~b)~~c) specification of a certain field in the given quantity (e.g. DC voltage measurements as a part of electricity voltage measurements, power of AC current at certain range of frequencies or power of DC current etc.);
~~c)~~d) measuring instruments (e.g. line length measuring instruments etc.);
~~d)~~e) measured medium (e.g. gas flow rate, liquid density etc.).

6.1.2 Each hierarchy scheme for measuring instruments should deal with measuring instruments of one quantity or some interrelated quantities. If reference or working measurement standards of other quantities have to be used in the hierarchy scheme of the given quantity, it is recommended to include them in the scheme.

6.1.3 The hierarchy scheme for measuring instruments of a certain quantity may be divided into a number of autonomous schemes if it leads to its more efficient arrangement and more rational use.

6.1.4 When the hierarchy scheme is established, it is necessary to specify especially:

a) the measuring instruments capable of fulfilling the role of reference and working measurement standards for different values or for different ranges of values of the given quantity;
b) the number of levels of reference and/or working measurement standards; and
c) the methods and means of dissemination of units.

Note: When establishing or reviewing a hierarchy scheme, the relevant authority should review and take into account the experience gained from the operation of existing schemes, at both national and international levels. In this comparative analysis, consideration should be given to the economic and societal context in which the new or revised scheme will be established, to ensure that any such experiences are applicable.

6.1.5 The choice of measuring instruments capable of fulfilling the role of reference and working standards is determined by the appropriate level of their metrological and technical characteristics in accordance with the specification stated in OIML D 8 [5].

6.1.6 In order to technically and economically optimise the benefits of the hierarchy scheme the number of levels of reference and/or working standards should be determined by considering at least the following:

a) the overall number of measuring instruments of the given quantity as regards the ~~kinds~~types of measuring instruments and their metrological characteristics;
b) the measuring instruments capable of fulfilling the role of reference and working measurement standards of different accuracy levels, their productivity and the mean values of the intervals between calibrations and the existence of proper methods and means of dissemination of units; and

c) the cost of ~~the~~ equipment, use and conservation of measurement standards and the means of dissemination of units, etc.

6.1.7 The method of calibration indicated in the hierarchy scheme should correspond to one of the following general methods:

a) direct measurements:
   – used in verification or calibration of an indicating measuring instrument against a ~~standard~~material measure; or
   – used in verification or calibration of a material measure against ~~a standard~~an indicating measuring instrument;
b) direct comparison ~~or comparison using a measure (standard comparison):~~:
   – used in verification or calibration of ~~a~~ an indicating measuring instrument against ~~a standard~~an indicating measuring instrument;
c) comparison with the help of a comparator:
   – used in verification or calibration of a material measure against a ~~standard~~material measure;
d) indirect measurements:
   – used in calibration or verification of a ~~measure or~~ measuring instrument using other measurement standards calibrated in terms of other physical quantities related functionally with the measurand.

6.1.8 For the calibration of measurement standards and measuring instruments or for the verification of measuring instruments, the characteristics of their uncertainty indicated in the hierarchy scheme are defined by calculations taking into consideration the characteristics of the total uncertainty of the higher-level measurement standard and methods for the dissemination of the unit.

6.1.9 For the verification of measuring instruments to determine their compliance with the specified requirements, the recommended ratio of the ~~total~~expanded measurement uncertainty ~~of the measurements~~ to the MPE is 1:3 or better (e.g. 1:10).

~~*Note:* Uncertainty of the measurement means the total uncertainty of all associated measurements carried out in the verification by means of measurement standards and/or measuring instruments.~~

6.2 Structure of hierarchy schemes

6.2.1 A hierarchy scheme consists of the graphic part of the scheme and a commentary on the scheme.

6.2.2 The graphic part provides a visual preview of the metrological traceability by listing the measuring instruments, including only basic information on some important characteristics. If the graphic part is too large and complicated, it is possible to divide it into sections, while the commentary remains common.

6.2.3 The commentary to the hierarchy scheme contains items such as explanations, hierarchy levels, metrological traceability, methods for placing measuring instruments, recommendations and comments. See 7.4 for the details of its contents.

6.2.4 National hierarchy schemes are usually divided into four fields:

a) national measurement standards field;
b) reference measurement standards field;,
c) working measurement standards field;
d) measuring instruments field.

In local hierarchy schemes the national measurement standards field is usually omitted.

6.2.5 The field of working measurement standards can be divided into a number of levels according to accuracy.

Note: Levels of working measurement standards may by indicated by Arabic numbers where the 1st level mark belongs to the measurement standards of the highest level in the hierarchy.

6.2.6 Measuring instruments used as standards in the field of measuring instruments can be divided into a number of levels according not only to their ~~kinds~~types but also to their accuracies and measurement ranges.

7 Contents and practical realisation of hierarchy schemes

7.1 Content of a national hierarchy scheme

The national hierarchy scheme for a certain ~~kind~~type of measuring instrument contains:

a) the name of the scheme, nominal values or ranges of values of quantity;
b) the recommended ~~kinds~~types of measuring instruments capable of fulfilling the role of a measurement standard at different accuracy levels and measurement ranges, typical measuring instruments (~~kinds~~types of verified or calibrated measuring instruments);
c) the recommended methods and means of dissemination of units between the measurement standards themselves and the measuring instruments (methods of calibration, calibration devices);
d) the recommended graduation of the accuracy level (uncertainties) of the reference and working measurement standards and the measuring instruments; and
e) the links between the elements of the scheme.

7.2 Content of a local hierarchy scheme

7.2.1 The local hierarchy scheme for a certain ~~kind~~type of measuring instrument contains:

a) the name of the laboratory, and the reference and working measurement standards which are traced to the national measurement standards;
b) all the elements of the laboratory's metrological traceability (reference and working measurement standards, measuring instruments, means of dissemination of units);
c) the range of measurements (nominal values or ranges of values of quantities, ranges of the most important conditions of measurements which define the procedure for the dissemination of the units) of all the measurement standards and measuring instruments indicated in the hierarchy scheme;
d) the estimation of the accuracy (uncertainty) characteristics of all the measurement standards, methods and means of dissemination of the units used;
e) all the links used between the elements of the laboratory's metrological traceability (verification or calibration procedures used);
f) the intervals between the calibrations of the measurement standards; and
g) the links between the elements of the scheme.

7.2.2 The local hierarchy scheme for (a) given ~~kind~~type(s) of measuring instruments, along with the measurement procedures for the measurement standards included in the scheme, has to unambiguously demonstrate that all the requirements for metrological traceability in accordance with the relevant regulations and guidelines are fulfilled in the given laboratory.

Note: If the reference measurement standards are directly used for legal control or calibration of ordinary measuring instruments, then they also act as working measurement standards.

7.3 Graphic part of a hierarchy scheme

7.3.1 The name of the hierarchy scheme is usually given in the header. The fields for the national measurement standard, the reference and working measurement standards and for the measuring

instruments should be separated in the graphic part of the hierarchy scheme by full lines. A description of the individual fields of the scheme is usually on the left side of the scheme. Horizontal dashed lines separate the individual levels of the standards in the working measurement standards field.

7.3.2 The measurement standards and measuring instruments should be presented as rectangles. The designation of the primary standard may be enclosed in a rectangle formed by a double line.

7.3.3 The methods and means of calibration and verification should be presented either in the measurement standard field to which a comparison is made, or at the lower border of this field as ovals.

7.3.4 The graphical representation of the procedure for disseminating the units should be performed in accordance with the following principles (see Annex C for examples):

a) if the calibration or verification of the measurement standard or measuring instrument is carried out by means of two or more measurement standards, solid lines representing the dissemination of the value of the unit (units) to an object of calibration are connected together into a point (e.g. item 8 of Annex C);
b) if the calibration or verification of a measurement standard or measuring instrument can be performed by means of any of the two or more methods or by the standards indicated in the scheme, then the solid lines representing the dissemination of the value of the unit are not connected into a point (e.g. item 6 of Annex C);
c) intersection lines (to be avoided if possible) are to be shown by a symbol, as shown in item 1 of Annex C.

7.3.5 The form of ~~expressing~~numerical expression (using an absolute or relative value) for the metrological characteristics ~~(absolute or relative)~~ of the measurement standards and/or measuring instruments in a single hierarchy scheme should be as similar as possible.

Note: For example, expressions with gram and percent should not be mixed.

7.3.6 The description given in the graphic part of the local hierarchy scheme should contain the following data, especially:

a) for the measurement standards: ~~kind~~type and name of the measurement standard, identification number of the measurement standard, measurement range, metrological characteristics specifying the measurement standards, the lower limits of the admitted values of the characteristics of their uncertainty, the range of the special condition of measurements;
b) for the methods and means of dissemination of units: name of the method, name and identification number of the means of dissemination of the units, characteristics of the uncertainty of the method;
c) for the measuring instruments: ~~kinds~~types of the verified or calibrated measuring instruments, their measurement ranges and basic metrological characteristics ~~(accuracy class, maximum permissible error, etc.)~~.

7.3.7 A simplified example of a national hierarchy scheme which contains three levels of measurement standards and the field of measuring instruments is given in Annex A. An example of the graphic part of a detailed local hierarchy scheme is given in Annex B.

7.4 Commentary to the hierarchy scheme

7.4.1 The commentary to the hierarchy scheme should contain all the data concerning metrological requirements and notes, which are not included in the graphic part of the scheme for any other reason and which cannot be ignored from a metrological traceability point of view.

7.4.2 The specification of the reference and working measurement standards should at least contain data as follows:

a) name and identification of the measurement standard;

b) nominal value(s) or measurement range(s) of the quantity(ies) value(s) reproduced by the standard and the measurement conditions;
c) information on any important metrological characteristics of the measurement standard (accuracy class, errors, uncertainty of values of quantities reproduced by the measurement standard, time stability of standard etc.).

It is recommended to also include the following data in this specification:

a) name of the legal metrology laboratory or accredited laboratory to which the reference or working measurement standard is compared;
b) recalibration interval,
c) location of the measurement standard.

7.4.3 The specification of the methods, means and conditions of dissemination of the units should contain at least the following data:

a) means of dissemination of the units – name of device, manufacturer, serial or identification number, and basic metrological characteristics.
b) method of verification or calibration,
c) verification or calibration procedure,
d) uncertainty of verification or calibration,
e) specified measurement conditions of the verification or calibration (if necessary).

Note: Calibration devices which contain several function parts in one compact unit (e.g. multiquantity calibration devices with built in measurement standards for several quantities, multiquantity calibrators etc.) are usually calibrated as a whole. Such devices are usually a part of different working hierarchy schemes. The position of such a device in an individual scheme depends on its measurement ranges and its declared metrological characteristics.

7.4.4 The specification of the measuring instrument should contain at least the following data:

a) ~~kinds~~types of verified or calibrated measuring instruments and their measurement ranges,
b) metrological characteristics of the measuring instrument (accuracy class or maximum permissible errors, nominal range, instrument constant, discrimination threshold, resolution, stability, etc.).
