TITLE OF THE CD (English):
OIML D 11
General requirements for measuring instruments - Environmental conditions

TITRE DU CD (French):
OIML D 11
Exigencesgenerales pour les instruments de mesure- Conditions environnementales

Original version in: English
Explanatory note to the 2 CD
(Temporary section to be removed after finalization of the Recommendation)

After publication of OIML D11: *General requirements for electronic measuring instruments* in 2004 the test methods and manner of presentation were implemented in many Recommendations and thus has been of great support in harmonization and speeding up the production processes for these Recommendations. However soon after publication it appeared that many referred standards tend to be updated in quite short timeframes.

During the meeting of OIML TC 5/SC 1 (Electronic instruments) on 21–22 October 2002 in Delft this need for frequent regular updates of references to standards was already discussed and following a suggestion by participants the secretary of OIML TC 5/SC 1 produced an overview in OIML Bulletin Volume XLVI - Number 4 -October 2005 of the status at that time of the ISO and IEC Standards referred to in OIML D 11 (2004).

In a later stage it was concluded in discussion with the BIML Director on 22 September 2006, that publication as an Expert Report on the OIML web site would be more appropriate in which way a better availability and continuity in updating references would be supported. This resulted in the publication of Expert Report E 5:2006. A second update of this report: “Overview of the present status of the Standards referred to in OIML D 11 - General requirements for electronic measuring instruments (2004)” has been published in beginning 2010.

During the existence of OIML D11 it became more and more clear that it would be welcome when the title and scope of the document would be somewhat extended beyond the present restriction to electronic instruments only. In the published document scope and field of application some space for wider application was yet made, however the title is kept restricted.

In order to get to an adjusted title and scope a proposal for amendment was submitted by the secretariat of TC 5/SC 1 to CIML at its meeting in Sidney in 2008.

At the CIML meeting a proposal passed containing as the new document title:

“Environmental requirements for measuring instruments” (Exigences environnementales pour les instruments de mesure)

noting that:

“The present edition of D 11 gives OIML TCs/SCs the possibility to apply the relevant aspects of D 11 to non-electronic instruments, but on a strictly voluntary basis. Experience has shown that, reading the title of D 11, many people regard D 11 as dealing with electromagnetic compatibility only, and often insufficiently realize that it also covers for instance temperature, vibration and mechanical shock.”

And a new project was proposed by the secretariat for revising OIML D11, which also was approved by CIML in its meeting in Sidney in 2008. This project was accepted having the following scope, purpose and justification:

“The primary aim of this revision of OIML D 11 is to update the standards referred to therein. This revision is also the ideal opportunity to clarify the scope of D 11 by changing its title from “General requirements for electronic measuring instruments” to “Environmental requirements for measuring instruments”. Furthermore, this revision might include other improvements like, for instance, a better separation between requirements and tests. OIML D 11 was published in 2004, so the review period of 5 years has not yet expired. But sub-clause 3.7.2 of the OIML Directives for the Technical Work provides for the possibility to propose an earlier review.

In the opinion of the Secretariat and others, so many standards referred to in D 11 have since been changed or replaced (See also OIML E 5), that the time has come to start a revision.

And now the generally accepted philosophy is that the requirements in the OIML Recommendations shall, as far as possible, be independent of technology.

A clarification of the scope/field of application of D 11 could be achieved by modifying the title.”

In the time between this approval and the publication of this first draft several definitions used in D11 which were copied from the referred vocabulary (VIM) changed as a consequence of an extensive update of this vocabulary.
Furthermore some test methods needed to be amended and at least a few additional tests needed to be implemented to keep compliance with recent innovations and the changes in mainly electromagnetic environment and to mend detected leaks in coverage by the test methods included in OIML D11 (2004). Examples of such gaps are the lacking of methods for testing the immunity to disturbances caused by the increasing use of mobile and/or wireless communication means and instrumentation and distortions on mains power produced by e.g. power converters and adapters.

In the mean time also a personnel change at the Secretariat took place. By combining the input from collected notes of the former secretary and the gained information collected from TC 9/SC 2 and TC 12 meeting in 2009 as well as the TC1 (VIML) meeting in 2010 with the secretariats background knowledge on EMC the preparation of the present Committee Draft was taken up. Main attention concerned the producing of quite a number of proposals for amendments, which below are summarized in general terms:

- modification of terminology as to comply with the new (2010) edition of the “VIM”;
- amending of definitions in order to harmonize with updated vocabularies (VIML(in revision) and VIM) and to converge terminology used such that it can be adapted in most Recommendations including those yet quite deviating;
- modification of terminology in such a way that redefining single words having a different meaning in every day English (US and UK) is as much as possible omitted;
- removing the subjective term “severity” where “level” is more applicable and introduction of use of “index” where stepwise increasing indexing is concerned;
- removing mix up of wording “applicable” and “relevant”;
- use of “electromagnetic” where applicable instead of “electrical”;
- introduction of environmental class E3 non-mains local source of electrical power supply;
- more logical rearrangement of tables in Clause 12-14. (On basis of EM frequency spectrum);
- updating of almost all referred references. (Since the publication of revised VIML [1a] and ref [26] is expected before or at about the same moment as the revised OIML D11, to be updated just before publication)
- attempts to reword vague formulated and grammatically incorrect clauses.

During the meeting of TC 5/SC 1 in June 2011 in Utrecht (NL) the most critical topic and comments were discussed making use of the compilation of comments received and the synthesis of the secretariat (TC 5/SC 1/011/CCS and TC 5/SC 1/012/CCS).

As a result on the following topics amendments were made:

- Title: The title of the 2004 version was abandoned and a new title was suggested which was sanctioned at the CIML 2008 (Annex G of working documents). The new title may be misleading and be interpreted to establish the environment of a measuring instrument. The working Title in the 1 CD may have the same disadvantage. It was suggested by BIML to change the title similar to the TC and SC name to the title as presented on page 1.
- Some extra explanatory text was added to chapter 4.
- A figure was added better explaining the difference between NSFa and NFSd
- Table numbering was corrected to comply OIML B6-2
- Definitions restricted to those terms used in D11 a few terms covered with the same definitions by new VIM and draft VIML still are still (temporarily) maintained for avoiding confusion with the D11 (2004) definitions.
- Relation between “fault” and a disturbance added in the definition.
- Checking facility definition is modified, based on the decisions during the meeting.
- Definitions of Stand-alone battery and specimen were added

---

1 This amendment was not completely agreed upon during the TC 5/SC 1 meeting in June 2011. See meeting conclusions and further amendments.
• The clause 7 on initial verification was deleted since the topic is considered rather beyond the scope of OIML D11 and better be part of the general contents (template) for a Recommendation

• The uncertainty clause was updated in line with the more recent approach to uncertainty in testing (see clause 9.1.1)

• Clause 9.2 contained several inconsistencies and therefore was completely revised. A figure provided by Japan was added to visualize the sequences.

• As discussed during the June 2011 meeting the requirements for immunity to RF radiation was amended to adapt to the changes in density of mainly mobile communication means. Also the preferred test level for immunity to conducted RF was adapted to this increasing phenomenon.

• Two new tables were added on testing of mobile (vehicle battery powered) measurement instruments (E3) in order to comply the amendments of ISO 7637-2 and ISO 16750-2 and to provide in a test on “load dump” as yet being required in certain region(-s)

• Several references updated

Foreword

The International Organization of Legal Metrology (OIML) is a worldwide, intergovernmental organization whose primary aim is to harmonize the regulations and metrological controls applied by the national metrological services, or related organizations, of its Member States.

The two main categories of OIML publications are:

• International Recommendations (OIML R), which are model regulations that establish the metrological characteristics required of certain measuring instruments and which specify methods and equipment for checking their conformity; the OIML Member States shall implement these Recommendations to the greatest possible extent;

• International Documents (OIML D), which are informative in nature and intended to improve the work of the metrological services.

OIML Draft Recommendations and Documents are developed by Technical Committees or Subcommittees which are formed by the Member States. Certain international and regional institutions also participate on a consultation basis.

Cooperative agreements are established between OIML and certain institutions, such as ISO and IEC, with the objective of avoiding contradictory requirements; consequently, manufacturers and users of measuring instruments, test laboratories, etc. may apply simultaneously OIML Publications and those of other institutions.

International Recommendations and International Documents are published in French (F) and English (E) and are subject to periodic revision.

This Publication - reference OIML D 11, edition 2011 (E) – was developed by the OIML Technical Subcommittee TC 5/SC 1 Environmental conditions. It was approved for final publication by the International Committee of Legal Metrology in 2011.

OIML publications may be downloaded from OIML web site in the form of PDF file.

Additional information on OIML publications may be obtained from the Organization’s headquarters:

Bureau International de Métrologie Légale

E-mail: biml@oiml.org
Internet: www.oiml.org
1 Introduction

1.1 The primary aim of this International Document is to provide the OIML Technical Committees and Subcommittees with guidance for establishing appropriate metrological performance testing requirements for influence quantities that may affect the measuring instruments covered by International Recommendations. Furthermore, this International Document aims to provide guidance to OIML Member States in the implementation of OIML Recommendations in their national laws, in particular in their choice on the applicability and severity of performance requirements as far as not prescribed in the applicable Recommendation, but left to national legislation.

1.2 Based on information obtained from IEC and ISO standards and on the experience of experts who participated in its elaboration, this Document advises the OIML Technical Committees and Subcommittees on the prescription of requirements and the selection of the appropriate tests for measuring instruments, while taking into account the operational and environmental factors governing their use.

1.3 The influence quantity tests’ range and test level should be, when possible, selected from the levels proposed in this Document, taking into account the conditions of use of the instruments concerned, and the most recent IEC and ISO standards in the given field. Hence the approach in this International Document is to present an overview of validated and international accepted test methods. In principle the text of this Document should not be in conflict with these referred standards.

1.4 The OIML technical Committees and Subcommittees responsible for specific International Recommendations may:
   • Establish test procedures and special test levels (higher or lower) in Recommendations, different from those specified in the Document, if that would be more appropriate for specific measuring instruments or environments.
   • Utilize the expertise and knowledge of the OIML Technical Committees and Subcommittees or of other organizations to develop special test procedures and conditions not specified in OIML D 11.

2 Scope and field of application

2.1 This International Document specifies general metrological requirements applicable to measuring instruments concerning environmental influences and describes tests for verifying the compliance of an instrument with these requirements.

2.2 This Document shall be taken into account by the OIML Technical Committees and Subcommittees when establishing performance requirements and tests for a specific category of measuring instruments concerning their sensitivity to influence quantities.

Notes:
(1) This Document does not cover requirements for measuring instruments which are not related to external influence quantities and which are to be covered by the specific Recommendation. For example: requirements for zero-setting devices, totalizers, etc.

(2) This Document does not address aspects such as safety or emission of electromagnetic phenomena from measuring instruments. The requirements for these aspects are beyond the OIML scope and should be taken into account in accordance with the applicable international, regional or national regulations.

(3) This Document does not address aspects concerning transportation of the measuring instrument while not being in operation. Requirements concerning the transportation related durability handling and maintenance aspects are beyond the OIML scope.

(4) This Document does not address aspects of influence by remote protocols such as software routines. For those aspects the OIML document D31 is applicable.

3 Terminology
Unless otherwise stated in the following sub clauses, the terminology used in this Document conforms to OIML V 1 International Vocabulary of Basic and General Terms in Metrology (VIM) [1], and OIML V 2 International Vocabulary of Terms in Legal Metrology (VIML) [1a].

For the purpose of this International Document, the definitions and abbreviations given below apply:

3.1 **electronic measuring instrument**

instrument intended to measure an electrical or non-electrical quantity using electronic means and/or equipped with electronic devices.

Note: For the purpose of this Document, auxiliary equipment provided that it is subject to metrological control, is considered to be a part of the measuring instrument.

3.2 **module**

device performing a specific function or functions and (usually) manufactured and constructed such that it can be separately evaluated.

Notes:
(1) A module may be a complete measuring instrument (for example: counter scale, electricity meter) or a part of a measuring instrument (for example: printer, indicator).

(2) OIML B3 [2] contains the following definition for a “module”:
Identifiable part of a measuring instrument or of a family of measuring instruments that performs a specific function or functions and that can be separately evaluated according to prescribed metrological and technical performance requirements in the applicable Recommendation.

3.3 **device**

identifiable instrument or part of an instrument or of a family of instruments having an identifiable function or functions.

Notes:
(1) A device may be a stand-alone and complete measuring instrument (for example: counter scale, electricity meter) or a part of a measuring instrument (for example: printer, indicator).

3.4 **(measurement) error** [VIM 2.16]

measured quantity value minus a reference quantity value.

3.5 **error (of indication)** [VIML .? .?]

indicated quantity value of a measuring instrument minus a reference quantity value.

3.6 **maximum permissible error (of a measuring instrument)** [VIM 4.26]

extreme value of measurement error, with respect to a known reference quantity value, permitted by specifications or regulations for a given measurement, measuring instrument, or measuring system.

3.7 **intrinsic error** [VIML .? .?]

error of a measuring instrument, determined under reference conditions.

3.8 **initial intrinsic error**

intrinsic error of a measuring instrument as determined prior to performance tests and durability evaluations.

3.9 **fault**

difference between the error of indication and the intrinsic error of a measuring instrument as a consequence of a disturbance.

Notes:
(1) Principally, a fault is the result of an undesired change of data contained in or flowing through an electronic measuring instrument.

(2) From the definition it follows that in this Document, a "fault" is a numerical value which is expressed either in a unit of measurement or as a relative value, for instance as a percentage.
3.9a fault limit
value specified in the applicable Recommendation delimiting non-significant faults

3.10 significant fault
fault exceeding the applicable fault limit value

Note:
For particular types of measuring instruments some faults exceeding the fault limit may not be considered a significant fault. The applicable Recommendation shall state when such exception applies. For example the occurrence of one or some of the following faults may be acceptable:

(a) faults arising from simultaneous and mutually independent causes originating in a measuring instrument or in its checking facilities,
(b) faults implying the impossibility to perform any measurement,
(c) transitory faults being momentary variations in the indication, which cannot be interpreted, memorized or transmitted as a measurement result,
(d) faults giving rise to variations in the measurement result that are serious enough to be noticed by all those interested in the measurement result; the applicable Recommendation may specify the nature of these variations.

3.11 durability error
difference between the intrinsic error after a period of use and the initial intrinsic error of a measuring instrument.

3.12 significant durability error
durability error exceeding the value specified in the applicable Recommendation.

Note:
Some durability errors exceeding the value specified may still be considered not significant. The applicable Recommendation shall state when such exception applies. For example the occurrence of one or some of the following may be acceptable:

(a) the indication cannot be interpreted, memorized or transmitted as a measurement result,
(b) the indication implies the impossibility to perform any measurement,
(c) the indication is so obviously wrong that it is bound to be noticed by all those interested in the result of the measurement, or
(d) a durability error cannot be detected and acted upon due to a breakdown of the appropriate durability protection facility.

3.13 influence quantity [VIM 2.52]
quantity that, in a direct measurement, does not affect the quantity that is actually measured, but affects the relation between the indication and the measurement result

3.13.1 influence factor
influence quantity having a value which ranges within the rated operating conditions of a measuring instrument.
Notes:
(1) The rated operating conditions shall be in conformity with the applicable requirements specified in the applicable Recommendation
(2) The variation of an indication as a consequence of an influence factor is considered an error and not a fault.

3.13.2 disturbance
influence quantity having a value within the limits specified in the applicable Recommendation but exceeding the specified rated operating conditions of the measuring instrument
Notes:
(1) These limits to be specified in the applicable Recommendation shall be based on the probability of occurrence of the disturbing phenomenon within the environment of the measuring instrument.
(2) A disturbance typically is of stochastic nature
(3) In case the listed rated operating conditions of a measuring instrument do not include a range for the specific influence quantity the influence quantity is qualified as being a disturbance

3.14 **rated operating conditions** [VIM 4.9]
operating condition that must be fulfilled during measurement in order that a measuring instrument or measuring system perform as designed.

**Note**
Rated operating conditions generally specify intervals of values for a quantity being measured and for any influence quantity.

3.15 **reference conditions** [VIM 4.11]
operating condition prescribed for evaluating the performance of a measuring instrument or measuring system or for comparison of measurement results.

**Note**
Reference operating conditions specify intervals of values of the measurand and of the influence quantities.

3.17 **durability**
ability of the measuring instrument to maintain its performance characteristics over a period of use.

3.18 **checking facility**
facility that is incorporated in a measuring instrument to detect and act upon:
- events that otherwise will result in significant faults, and / or
- incorrect functioning of a specific device of the measuring instrument and/or
- disturbed communication between specific devices of the measuring instrument.

**Note:**
"Act upon" refers to any adequate response by the measuring instrument (luminous signal, acoustic signal, prevention of the measurement process, etc.).

3.18.1 **automatic checking facility**
checking facility that operates without the intervention of an operator.

3.18.1.1 **permanent automatic checking facility (type P)**
automatic checking facility that operates at each measurement cycle.

3.18.1.2 **intermittent automatic checking facility (type I)**
automatic checking facility that operates at certain time intervals or per fixed number of measurement cycles.

3.18.2 **non-automatic checking facility (type N)**
checking facility that requires the intervention of an operator.

3.19 **durability protection facility**
facility that is incorporated in a measuring instrument and which enables significant durability errors to be detected and acted upon.

**Note:** refer to note 3.18

3.20 **test**
series of operations intended to verify the compliance of the equipment under test (EUT) with specified requirements.

3.20.1 **test procedure**
detailed description of the test operations.

3.20.2 **test program**
description of a series of tests for certain types of equipment.

3.20.3 **test level**
required (simulated) influence quantity value for performing the test.

3.20.4 **performance test**
test intended to verify whether the EUT is able to accomplish its intended functions.
3.20.5 **durability test**
A test intended to verify whether the EUT is able to maintain its performance characteristics over a period of use.

3.21 **mains power**
primary external source of electrical power for an instrument, including all sub-assemblies.
(Examples: public power (AC or DC), generator, external battery or other DC supply systems)

3.22 **power converter (power supply device)**
sub assembly converting the voltage from the mains power to a voltage suitable for other sub-assemblies.

3.23 **Stand-alone battery**
non-rechargeable battery or rechargeable battery which shall be (re)charged only when not connected to the EUT

3.24 **auxiliary battery**
battery that is:
- mounted in, or connected to, an instrument that can be powered by the mains power as well, and
- capable of supplying power for the complete instrument for a reasonable period of time.

3.25 **back-up battery**
battery that is intended to maintain power supply for specific functions of an instrument in the absence of the primary power supply.
(For example: to preserve stored data)

3.26 **specimen**
instrument, device or module subjected to testing, examination or study and representing a population

3.27 **measurement uncertainty** [VIM 2.26]
uncertainty of measurement
uncertainty

non-negative parameter characterizing the dispersion of the quantity values being attributed to a measurand, based on the information used
(See VIM 2.26 for notes on the definition)

4 Instructions for use of this Document in drafting OIML Recommendations

The general structure of OIML Recommendations is defined in the OIML Basic publication B6-2 chapter 3, which is followed by a description in somewhat more detail. The following clauses concern the elaboration into more detail and instructions on the incorporation of these required elements in a Recommendation.

4.1 The applicable Recommendation shall specify, for each category or subcategory of measuring instruments:
(a) expected influence factors, with rated operating and reference conditions,
(b) expected disturbances and associated expected maximum intensity (limit of disturbance),
(c) maximum permissible errors on type evaluation, on initial verification, in service, and on subsequent verification, as well as significant fault level, and significant durability error level (wherever applicable).

4.2 The applicable Recommendation may specify additional requirements or adapt the requirements in this Document with a view to limiting the occurrence of the significant faults defined in 3.10.

Note:
These requirements may depend on the nature of the measurement (repeatable, non-repeatable, non-interruptible, etc.) or the intended use (trade, direct selling to the public, health, law enforcement, etc.).

4.3 The applicable Recommendation may specify requirements concerning the occurrence of durability errors defined in 3.11 (see note sub-clause 4.2).

4.4 Some ranges of measuring instruments may on basis of design principle be not susceptible to some specific influence quantities. For a particular kind of instrument it therefore shall only be required to perform the tests for which the instrument is likely to be influenced by the influence quantity during its operation.

4.5 Clause 8 of this Document contains guidelines for the determination of the test levels to be applied in the evaluation of compliance with the requirements specified in the applicable Recommendation.

4.6 All referenced standards and normative documents are subject to revision, and the users of this Document are encouraged to investigate the possibility of applying the most recent editions of these standards and documents.

Note:
The applicable Recommendation shall specify the rated operating conditions, reference conditions and limits of disturbances for the category of instruments concerned. However, the applicable Recommendation may indicate that individual subcategories of measuring instruments may have different rated operating conditions, reference conditions and limits of disturbances.
Rated operating conditions are generally specified as a range (for example: -10 °C to +40 °C); reference conditions are generally specified as a single value with a range of variation (for example: 23 °C ± 2 °C).
The reference conditions shall preferably be specified in accordance with IEC 60068-1 [3].

5 Requirements for measuring instruments with respect to their environment

Measuring instruments shall comply with the following requirements, notwithstanding all other technical and metrological requirements of the applicable Recommendations, when installed and used in accordance with the manufacturers’ specifications.

5.1 General requirements

5.1.1 Measuring instruments shall be designed and manufactured such that their errors do not exceed the maximum permissible errors under rated operating conditions.

5.1.2 Measuring instruments shall be designed and manufactured such that when they are exposed to disturbances, either:
(a) significant faults do not occur, or
(b) significant faults are detected and acted upon by means of a checking facility.

Note:
A fault equal to or smaller than the value fixed (fault limit) in the applicable Recommendation as defined in 3.10 is allowed irrespective of the value of the error of indication.
5.1.3 The provisions in 5.1.1 and 5.1.2 shall be durably met. Measuring instruments shall be designed and manufactured such that either:
(a) significant durability errors do not occur, or
(b) significant durability errors are detected and acted upon by means of a durability protection facility.

5.1.4 The type of a measuring instrument is presumed to comply with the provisions in 5.1.1, 5.1.2 and 5.1.3 if it passes the examination and tests specified in 6.2.

5.2 Application

5.2.1 The provisions in 5.1.2 (a) and 5.1.2 (b) may be applied separately to:
(a) each individual cause of significant fault, and/or
(b) each part of the measuring instrument.

5.2.2 The choice of whether 5.1.2 (a) or 5.1.2 (b) is applied is left to the manufacturer, unless the applicable Recommendation specifies otherwise in view of the intended use of the measuring instrument or the nature of measurement (see note sub-clause 4.2).

5.2.3 The provisions in 5.1.3 (a) and 5.1.3 (b) may be applied separately to each part of the measuring instrument (for example: analogue and digital parts).

5.2.4 The choice of whether 5.1.3 (a) or 5.1.3 (b) is applied is left to the manufacturer, unless the applicable Recommendation specifies otherwise.

5.3 Measuring instruments equipped with checking facilities

5.3.1 For each function of a measuring instrument the applicable Recommendation may specify:
(a) the kind of checking facility (P, I or N), as defined in 3.18,
(b) the checking frequency, if appropriate,
(c) the method of acting upon a significant fault.

5.3.2 The applicable Recommendation may specify that it shall be possible to determine the presence and correct functioning of these facilities.

5.3.3 The requirements in 5.3.1 and 5.3.2 do not apply to measuring instruments or parts of measuring instruments for which the manufacturer claims compliance with the provisions in 5.1.2 (a) and which are nevertheless equipped with checking facilities.

5.4 Measuring instruments equipped with durability protection facilities

5.4.1 The applicable Recommendation may specify:
(a) details concerning the operation of the durability protection facilities, and/or
(b) the method of acting upon the detection of significant durability errors.

5.4.2 The applicable Recommendation may specify that it shall be possible to determine the presence and correct operation of these facilities.

5.4.3 The requirements in 5.4.1 and 5.4.2 do not apply to measuring instruments or parts of measuring instruments for which the manufacturer claims compliance with the provision in 5.1.3 (a) and which are nevertheless equipped with durability protection facilities.

5.5 Requirements for battery powered instruments

5.5.1 Specification of batteries

Type(-s) and capacity(-ies) of the batteries allowed to be used in the applicable measuring instruments shall be specified by the manufacturer. Instruments not equipped with allowed batteries are considered not of the same type.

5.5.2 Stand-alone batteries
Instruments powered by stand-alone batteries shall comply with the following requirements:
(a) Instruments provided with new and fully charged batteries shall comply with the metrological requirements;
(b) The manufacturer of the measuring instrument shall specify the minimum battery voltage at which the instrument still complies the metrological requirements;
(c) In case the battery voltage has dropped below this minimum voltage level specified by the manufacturer this shall be detected and appropriately acted upon by the instrument. The applicable Recommendation may prescribe this manner of response.
(d) The battery capacity and lifetime shall be in accordance with the application. The applicable Recommendation may need to prescribe a required minimum lifetime.

For such instruments, tests associated with the mains power variations and interferences need not to be performed.
The applicable recommendation shall specify a minimum set of provisions to prevent the loss of stored data.

5.5.3 Rechargeable auxiliary batteries
Instruments powered by rechargeable auxiliary batteries that are intended to be (re)charged during the operation of the measuring instrument shall both:
(a) comply with the requirements of 5.5.2 with the mains power switched off, and
(b) comply with the requirements for mains powered instruments with the mains power switched on.

5.5.4 Back-up batteries
Instruments powered by the mains power and provided with a back-up battery for data-storage only, shall comply with the requirements for mains powered instruments.
In the applicable Recommendation a minimum period of time shall be stated during which the applicable function of the instrument shall function properly without renewing or recharging the batteries.
The provisions of 5.5.2(b) and 5.5.3 do not apply for back-up batteries.
6 Type evaluation

6.1 Application for type evaluation

6.1.1 The applicable Recommendation specifies the minimum set of documentation to be submitted together with the application for type evaluation. In the informative annex C a non-confined listing of required documentation is presented.

6.1.2 Furthermore, the application for type evaluation shall be accompanied by a document or other evidence that supports the assumption that the design and characteristics of the measuring instrument comply with the requirements of the applicable Recommendation, in which the general requirements of this Document have been incorporated.

6.2 General requirements

The applicable Recommendation shall include the following examinations and tests to verify compliance with the general requirements for measuring instruments:

(a) examination to verify whether the measuring instrument complies with the provisions in 5.1,
(b) performance tests to verify compliance with the provisions in 5.1.1 and 5.1.2, regarding influence quantities.
(c) durability evaluation (i.e. tests and/or other means) to verify compliance with the provisions in 5.1.3,
(d) examination and tests to verify compliance of the electronic measuring instrument with the provisions in 5.3, 5.4, and 5.5 if applicable.

All measuring instruments of the same category whether or not equipped with checking facilities and whether or not equipped with durability protection facilities, are subject to the same test program, unless the applicable Recommendation specifies otherwise. The test program shall be specified in the applicable Recommendation, according to the operating conditions of the category of measuring instruments.

6.3 Instrument performance tests

During performance tests the EUT shall be operational (i.e. the power shall be switched on), except in case the test procedure in this Document or in the applicable Recommendation specifies otherwise and shall comply with:

(a) the provisions in 5.1.1, the maximum permissible error being the maximum permissible error on type evaluation, and
(b) the provisions in 5.1.2.

6.4 Instrument durability tests

In case a durability test is to be performed, the performance tests shall be carried out before the durability test. The Recommendation shall further specify which specific performance test(s) shall be repeated after the durability test.

During performance tests carried out after each durability test, the measuring instrument shall comply with the provisions in 5.1.3.

Note: After each durability test, only performance tests that are relevant to the durability test concerned shall be carried out.

6.5 Test program

The applicable Recommendation may specify details concerning the test program, including:

(a) which tests shall be performed,
(b) the order in which the tests are to be performed (if necessary, taken into account the technology),
6.6 Test procedures

6.6.1 The test procedures of the most common performance tests are specified in Chapters 9 - 14. Annex B provides a general approach to the durability concept.

6.6.2 The applicable Recommendation shall specify:
(a) necessary details concerning the tests, including those already stated in Chapters 9 - 14,
   Note: As a rule, only one influence quantity may be varied during a test, while all others shall be kept at their reference values.
(b) required severity and associated test levels in accordance with the classification laid down in clause 8, where applicable, and
(c) allowed deviations from the described tests, if necessary. (For example, a limited temperature range for a measuring instrument may lead to modification of the static temperature performance test.)

6.7 Number of specimens to be submitted to tests

The test shall be performed on the number of specimens as specified in the applicable Recommendation.

6.8 Test arrangement (Equipment under test (EUT))

As a rule, tests shall be carried out on the complete measuring instrument. If the size or configuration of the measuring instrument does not allow for testing the complete EUT or if only a separate device or module of the measuring instrument is concerned, the applicable Recommendation may indicate that the tests, or certain tests, are allowed to be performed on the devices separately while making use of an instrument simulating set-up, sufficiently representing its normal operation.

In such cases the device(s) need(s) to be in operation.

Note: It is not intended to dismantle the measuring instruments or devices for the cause of testing.

7 Determination of test levels

8.1 Introduction

8.1.1 This clause is intended as a guideline for Technical Committees and Subcommittees for determination of the test level as to verify the sustainable compliance of measuring instruments with their metrological requirements in their applicable operating and storage environment.

This determination is not intended as a classification with strict boundaries leading to special requirements like in the case of an accuracy classification.

Moreover, this guideline does not interfere with the liberty of the Technical Committees and Subcommittees to provide for test levels that differ from those resulting from the other guidelines set forth in this Document. Different test levels may be used in accordance with special limitations prescribed in the applicable Recommendations.

8.1.2 The environment determining parameters of interest being most common to measuring instruments could be split into three main groups, which are generally considered mutually independent:
(a) those establishing the climatic environment,
(b) those establishing the mechanical environment, and
(c) those establishing the electric, magnetic and electromagnetic environment.

All measuring instruments will encounter variations in the environment as a consequence of normal changes in magnitude of one or more of the parameters mentioned. Since the presented environment determining parameters generally are mutual independent, an overall single classification based on increasing severity is not possible. For each of these three main groups therefore a separate classification is made. The classification subsequently will serve in choosing the adequate test level

Notes:
(1) The applicable Recommendation may require that the classification be indicated on the instrument.

8.1.3 When selecting the level of immunity needed for environmental phenomena and the associated test levels for a particular category of instruments, the following aspects are to be taken into account:
(a) the (typical) climatic, mechanical and electro-magnetic environment,
(b) the consequence and the social and societal impact,
(c) the value of goods to be measured,
(d) the practical possibilities for the industry to comply with the prescribed level, and
(e) the possibility to repeat a measurement.

8.2 Ambient classification and associated required severity of the climatic tests

Several environmental classes covering most of the different climatic ambient conditions at the locations where measuring instruments are used have been defined as described below.

This classification and the associated preferred test levels, based on this classification are presented in table 1. Extreme conditions are not included; since the probability of occurrence of such conditions is considered low. An incidental occurrence of such an extreme situation is to be interpreted as being a disturbance.

8.2.1 Temperature

The ambient temperature of a measuring instrument in use may vary considerably. This is highly dependent not only on the place on earth, ranging from arctic to tropical regions, but also considerably on indoor or outdoor use. Instruments typically being used indoors in one country may typically be in use outdoors in another country (for instance gas meters and electricity meters in residential environment). Therefore, no classification based on temperature ranges has been described in this Document.

In general, the choice on the lower and the upper temperature limits should preferably be left to national (or regional) legislation. When applying tests in order to verify the compliance with the required temperature range, the test levels should be in conformity with those specified in the tables 6 and 7.

8.2.2 Humidity and water

Table 1 presents the classification of the ambient concerning exposure to humidity and water and indicates the applicable test method and test level index:

<table>
<thead>
<tr>
<th>Class</th>
<th>Test level index</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Damp Heat</td>
<td>Water (Table 10)</td>
</tr>
<tr>
<td>Steady state Table 8</td>
<td>Cyclic (Table 9)</td>
<td></td>
</tr>
</tbody>
</table>

This class applies to those instruments or parts of instruments typically being used in temperature-controlled closed (weather protected) locations. The local humidity is not controlled. Where necessary heating, cooling or humidification is used to maintain the required environmental conditions, Measuring instruments are not exposed to condensed water, precipitation, or ice formations.

These environmental conditions may apply in living rooms, continuously staffed offices, certain workshops, and other rooms for special applications.
This class applies to those instruments or parts of instruments typically being used in closed (weather protected) locations where the local climate is not controlled. Measuring instruments present may be subjected to condensed water, water from sources other than rain and to ice formations. These environmental conditions may apply in some public available areas in buildings, in garages, cellars, certain workshops, factories and industrial plants, ordinary storage rooms for frost-resistant products, farm buildings, etc.

This class applies to instruments or parts of instruments used in open air locations excluding those in extreme climate zones like polar and desert environments.

Note: A comparison between steady-state and cyclic tests is presented in IEC 60068-3-4 [15].

The requirement for immunity to water exposure is mainly applicable to those instruments or parts of instruments typically being used in the open air and that, in their normal use, could be directly exposed to spraying water (rain, etc.). Examples are platforms of weighbridges or automatic radar speed measuring instruments.

It is advised to therefore only require this class of water protection and implement the associated performance test - specified in sub-clause 10.3 - in the Recommendations applicable to those measuring instruments which typically will be used in an environment where such exposure to water may be expected (see sub-clause 4.4).

8.2.3 Atmospheric pressure (Table 11)
Considering the ranges and variations in global terrestrial atmospheric pressure, only a few categories of measuring instruments due to their physical principles are likely to be influenced by these changes. This influence could either be on the zero-indication of the instrument (offset), on the span (curve) or on both.
It is advised to therefore only require the evaluation of performance on atmospheric pressure variation in those Recommendations that are applicable to measuring instruments which typically, due to their physical measuring principle, are expected to be sensitive to variations in atmospheric pressure (see 4.4).

8.2.4 Sand and dust (Table 13)
Referred test is mainly applicable to those instruments or parts of instruments typically being used in dusty warehouses and building industry (for instance production of concrete) or, in some climatic regions, in the open air.
It is advised to therefore only require a measure of protection to withstand this influence and consequently implement the performance test specified in sub-clause 10.5 in those Recommendations that are applicable to measuring instruments that can be expected to be used under sandy/dusty conditions (see sub-clause 4.4).

8.2.5 Salt mist (Table 14)
Referred test is mainly applicable to those instruments or parts of instruments that are typically used in a humid salt water environment. Examples are measuring instruments on board of sea-going vessels or used in the cheese producing industry. It is advised to therefore only require a measure of protection to withstand this influence and consequently implement the performance test specified in sub-clause 10.6 in those Recommendations that are applicable to measuring instruments that can be expected to be typically used in a humid and salt environment (see sub-clause 4.4).

8.3 Ambient classification and associated required severity of mechanical tests
Table 2 presents the classification of the ambient of measuring instruments concerning exposure to vibration and shocks at its location of operation and indicates the applicable test method and test level index

<table>
<thead>
<tr>
<th>Class</th>
<th>Test level index</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Vibration (table 15 and 16)</td>
<td>Shock (Table 17)</td>
</tr>
<tr>
<td>M1</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

This class applies to locations with vibration and shocks of low significance, e.g. for instruments fastened to light supporting structures subject to negligible vibrations and shocks transmitted from local blasting or pile-driving activities, slamming doors, etc.
This class applies to locations with significant or high levels of vibration and shock, e.g. transmitted from machines and passing vehicles in the vicinity or adjacent to heavy machines, conveyor belts, etc.

This class applies to locations where the level of vibration and shock is high or very high, e.g. where measuring instruments are directly mounted on machines, conveyor belts etc.

In sub-clause 11.1, two vibration tests (random and sinusoidal) have been described. In general, it should be avoided to prescribe both tests in OIML Recommendations.

Since vibration of a random nature is real life practice, it is expected that a performance test on the sensitivity of measuring instruments to random vibration covers the requirement for withstanding influences by environmental vibrations and should be the most commonly prescribed performance test in OIML Recommendations. The sinusoidal test shall be prescribed and applied only in those cases where the measuring instrument is expected to be typically subjected to sinusoidal vibrations.

For the selection of the appropriate test (random or sinusoidal) refer to IEC 60068-3-8 [16]; in particular to (sub)clauses 4.2, 7, 8.3, and 8.4 of that standard.

It is strongly recommended not to try to convert sine vibration to random vibration or vice versa. There is no simple physical relationship between the two. The impact on the specimen will therefore be different.

Note: Requirements concerning the transportation of a measuring instrument are outside the scope of this Document.

8.4 Classification of EM environment and the associated required severity of electro-magnetic tests

A classification is made to help in selecting the most adequate requirements and associated performance test concerning electro-magnetic influences and interferences.

As far as electro-magnetic related phenomena are concerned this classification will need to depend on the expected electro-magnetic environmental conditions of the measuring instrument and on its application. (see sub-clause 8.1.3)

These conditions depend on the specific environment where the instrument is expected to be installed (residential, general public, commercial, industrial etc.), the concept of the measurement system and the use of the measurement system.

A discrimination in electro-magnetic environment could be made on basis of differences in:

- either the kind of potential electro-magnetic influence quantity in the environment and their intensity, or the available potential entering paths of the influence quantity, which in turn are defined by the concept of measuring instrument or system. Furthermore one could distinguish between concepts with a more closed (isolated) structure and those with a more open electromagnetic architecture. In the latter case cabling lay-out of the instrument or system can be quite of influence to the sensitivity for influence quantities.

For feasibility reasons and while for most instruments the above discrimination is not trivial, a discrimination will be made only between 3 (electro-magnetic) classes and the associated requirements and test methods are presented for only a limited number of potential sources of influence (which are considered to be the main potential electrical influence quantities).

The following groups of influence quantities are to be considered:

1. those caused by conducted EM phenomena (transmitted through power or data lines),
2. those caused by radiation of EM phenomena (non-guided transmission)

(Both these influences could originate from all kind of sources, for example: remote instrumentation, some action of personnel or atmospheric disturbances)

Table 3 presents the classification of the ambient of measuring instruments concerning their electro-magnetic environment at its location of operation:

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
</table>

Note: Requirements concerning the transportation of a measuring instrument are outside the scope of this Document.
This class applies to measuring instruments used in locations where electromagnetic disturbances correspond to those likely to be found in residential, commercial and light industrial environment.

This class applies to instruments used in locations where electromagnetic disturbances correspond to those likely to be found in industrial buildings.

This class applies to measuring instruments powered by the battery of a vehicle and exposed to electromagnetic disturbances which correspond to those likely to be found in any environment not considered hazardous for general public.

table 4 presents the references to the test method and test level to be applied, taking into account the classification of the electro-magnetic environment.

The conditions have been adapted from the basic Publication IEC/TR 61000-2-5 [26]

Guidance to test level choice

Some extra guidance for choosing the measure of immunity and the associated test level for some specific tests concerning electro-magnetic environment is presented in the following sub-clauses 8.4.1 - 8.5.2. This information is provided as guidance to TC’s and SC’s and their secretariats only, giving some background on the choice of tests and the suggested test levels.

8.4.1 Ripple on DC mains power (Table 19)

No requirements for class E1 and E3 have been suggested while this test only applies to DC mains power networks which are almost exclusively applicable in industrial environments.

8.4.2 AC mains frequency variation (Table 20)
In general the public AC mains supply networks are coupled resulting in negligible variations in the frequency. Only in remote areas and in case of local generators, the frequency changes can be of significance. Therefore it is advised to only prescribe this test in OIML Recommendations in those cases where as a result of the physical principle of the measuring instruments, the frequency of the AC mains supply can have a significant influence on the performance of the instrument, for instance in the case where an internal time-base of the instrument is derived from the mains power frequency. (also refer to 4.4).

8.4.3 Voltage dips, short interruptions and (short term) voltage variations on DC mains (Table 22)
No requirements for class E1 and E3 have been suggested while this test only applies to DC mains power networks which are almost exclusively applicable in industrial environments.

8.4.4 AC mains voltage dips, short interruptions and voltage variations (Table 23)
Occurrence of voltage dips in AC mains power supply networks is rather standard. Moreover interruptions for half a cycle or less are characteristic. A measuring instrument shall need to withstand and be more or less immune to such dips and interruptions in order to comply with the provisions of 5.1.1.

To evaluate the compliance of performance with these provisions the presented level 2 is considered the minimum test level required.

The occurrence of voltage dips and short supply interruptions in general cannot be predicted. Especially in the industrial environments these may occur and persist for a relative long period of time. It is reasonable to require instruments, intended to be used in an industrial environment, to withstand such dips and interruptions and consequently require them to be submitted to performance tests up to a level 3 in order to avoid the risk on frequent interruption of instrument performance.

When, on basis of the classification of the environment, test level 2 applies three tests are to be performed and in case test level 3 applies five tests are to be performed, all 3 or 5 tests presented in the applicable test level column need to be implemented in the applicable Recommendation since the response or failing of the EUT on one of the tests cannot be predicted from the responses on the other tests.

8.4.5 AC mains frequency harmonics (Table 24)
Through the increasing use of small transformers and semiconductor switching devices in power converters, lighting systems, AC/DC converters, UPS systems and rectifiers the distortion of public power supply networks has increased. Power supply companies are obliged for several reasons to keep the level of disturbance beneath certain limits. For harmonisation reasons for each harmonic an environment dependent compatibility level has been established. Immunity test levels require a certain margin. In IEC 61000-4-13 a factor 1.5 was used to create this margin. The requirement of immunity and associated test shall be implemented in OIML Recommendations for measuring instruments which tend to be connected to an AC mains network.

In the standard a further subdivision is made in the class E1 environment. Only in pure residential environment the test level index 2 is yet considered applicable. For industrial and commercial environment the test level indexed 3 applies.

Typical environments where relative high level mains electromagnetic mains power harmonics can be expected are:
- heavy industry (chloride production plants)
- high capacity rectifier stations

8.4.6. VLF and LF disturbances on mains power lines (Test under consideration)
Through the increasing use of power line communication (PLC) and switching semiconductors in power supply systems VLF and LF differential mode disturbances tend to interfere with the mains power supply sine wave. Moreover PLC and semiconductor switching devices tend to interfere with each other. Especially in those cases where the waveform of the mains power line could be directly of influence to measuring instruments (like electrical energy meters) these tests should be applied.

8.4.7 Bursts (transients) (Table 26 and Table 28)
The selection of the applicable immunity and the associated test level shall be based on the expected use of the measuring instrument and presented in the applicable Recommendation.
Test level 1 applies to instruments operating in environments well-protected against electro-magnetic interferences (e.g. computer rooms); test level 2 applies to instruments operating in areas with a normal level of protection (class E1); and test level 3 applies to instruments operating in areas without special protection measures (e.g. industrial plants, class E2).

8.4.8 **Surges** (Table 27 and Table 29)

The requirement on immunity to surges is applicable to all situations where the measuring instrument will be connected to the (AC or DC) mains power lines. In general the requirement also applies where data cabling is connected. For deciding on whether there is a need for testing all connected network cabling needs to be taken into account. Exclusively in those situations where the interconnecting cabling between devices will never exceed the length of 10 m testing is not applicable. Where applicable the requirement and associated tests shall be implemented in OIML Recommendations.

8.4.9 **Mains power frequency (electro) magnetic fields** (Table 30)

This test shall only be prescribed as required in those OIML Recommendations where a significant influence from external power frequency magnetic fields on the measurement results may be expected, as a consequence of the physical principle of the measuring instruments concerned. This includes instrumentation equipped with touch switches, (also refer to sub-clause 4.4)

This test does not cover the frequency spectrum of harmonics of the power frequency, which fields normally are more common and intense.

**Notes:**
1) The WHO advises a protection level for whole body human exposure (general public) of 80 A/m (50Hz) and of 400 A/m for occupational exposure (workers).
2) Small sources like many types of the adapters used to power or load battery powered equipment tend to create electromagnetic fields exceeding the 80 A/m level, but these power frequency EM fields tend to diminish very rapidly with distance and only a few centimetres from the source could be reduced to 1 % of the original level.
3) Typical environments where relative high level mains electromagnetic field strength can be expected are:
   - high and medium voltage mains power lines
   - heavy industry
   - static power converters (transformers)
   - induction cooking

8.4.10 **Radiated RF electromagnetic fields and resulting induced RF currents**

(Tables 31,32, 33,34)

The rationale for the advised test levels as presented in the tables 31-34 is as follows:

The frequency range presented in table 33 is in use for many services It also covers the VHF and part of the UHF broadcast transmitter bands. The maximum level of field strength which can be expected near to these transmitters may in the general public area exceed the level of 10 V/m, but may be expected not to exceed the maximum exposure levels for human beings (general public) as advised by the WHO and implemented in the national legislation of quite some nations. Up to 400 MHz this maximum level is 27.5 V/m, linear increasing with frequency from 400 MHz to about 45 V/m at 1000 MHz. Although such high field strength levels may be expected in the neighbourhood of fences around transmitter sites this still is not a sufficient argument to choose for a test level beyond 10 V/m while one should take into account the general incidental character and the probability of an actual unintentional distortion of the measurement due to the fact that the following risk reducing factors apply:
- the field strength near to a transmitter reduces about with the square of the distance to the transmitter.
- the optimum coupling (influence) only occurs when polarization of source (transmitter) and sensitive part or element of the exposed object (acting as receiver) are in parallel and the transmission direction of the transmitter (perpendicular to the polarization) is in line with that of the receiver.

The unforeseen incidental exposure to the above mentioned levels therefore may probably only apply in the case whe a mobile measuring instrument in operation passes such a powerful broadcast transmitter.

The frequency ranges in table 34 typically apply for digital mobile phones. To get some impression on applicable field strength levels one should be aware that:
- a 2 W GSM phone typically produces a field strength of 10 V/m (modulated wave) at a distance of 1 m from the transmitter. For an 8 W GSM this distance will be 2 m.
- a 200 W GSM base station typically produces a field strength of 10 V/m (modulated wave) at a distance of 10 m. For more details, please consult table G.1 in IEC 61000-4-3 [29].
The maximum level of field strength which can be expected near to these radiating sources may in the general public area exceed the level of 10 V/m, but may be expected not to exceed the maximum exposure levels for human beings (general public) as advised by the WHO. This maximum level of 27.5 V/m up to 400 MHz is linear increasing with frequency from 400 MHz to 61 V/m at 2 GHz and is limited to 61 V/m level in the frequency range above 2 GHz. Therefore the tests to be applied and specified in the applicable Recommendation cannot be related to only one specific environment. So in order to verify compliance with the electromagnetic environment of use, the tests shall extend to a frequency range and an intensity level that merely depend on:
- the possibility of a mobile telephone being used in close vicinity of the instrument or
- the location of a base station relative to the instrument,
- the risk of fraud by using a mobile phone as source of disturbance, and
- the consequences of an error or disturbance.

In the frequency band between 3 and 6 GHz the following should be taken into consideration:
The larger radiating sources in this frequency band mainly concern amateur radio stations creating field strengths in the bands 3.3-3.5 GHz and 5.65-5.93 GHz up to 30 V/m at 10 m distance. (see IEC/TR 61000-2-5 Table 25 [26] ) This however concerns transmission using narrow beam antennas such as dish antennas in use for dish to dish beam connections including satellite uplinks. Only in the main beam if the antenna this level of field strength may be measured.

8.4.11 Electrostatic discharge (Table 35)
Since the human body may be charged to a maximum value of 15 kV in extreme conditions (very low relative humidity combined with synthetic fabrics and use of synthetic footwear), ESD tests of test level 4 will only be necessary for instruments to be used under circumstances where such conditions are likely to exist. Measurement instruments that will be used in areas where the relative humidity exceeds 50 % should be tested by exposure up to and including the test level 3.

8.5 Additional guidance for battery powered instruments
For selecting tests for battery powered measuring instruments a distinction is to be made on basis of kind of battery applied. These different types are:
(a) disposable batteries,
(b) general rechargeable batteries, and
(c) batteries of road vehicles.

8.5.1 In case of disposable and rechargeable batteries of a general nature, at present no standards can be referred to. The requirements are described in brief in sub-clause 5.5 and the applicable tests in table 36

8.5.2 For instruments powered by the on board battery of a road vehicle (environmental class E3), a series of special tests simulating disturbances associated with the road vehicle power supply is presented in the sub-clause 13.2 of this Document. These tests are based on the International Standards series ISO 7637 [41-43] and ISO 16750-2 [40] According to clause 4 of ISO 7637-1 [41], this series of standards “provides a basis for mutual agreement between vehicle manufacturers and component suppliers, intended to assist rather than restrict them.”

Measuring instruments that are designed to be mounted on board a road vehicle in generally could be mounted on any kind of vehicle. Therefore, in the tables 37 and 38 of this Document, only the most severe level of testing specified in the standard is indicated as being the preferred level.

The choice of the test level to be applied is not related to a specific environment, but merely by the impact of a disturbance and, where relevant, to the electromagnetic properties of the specific type of vehicle in which the instrument is used.

The applicability of the test presented in table 39 “Electrical transients conduction via other than supply lines” strongly depends on cable length and lay out of the I/O lines. In case the I/O lines of the applicable measuring instruments, are limited to less than 0,5 m it is advised not to implement these test.
The Capacitive Coupling Clamp method described in the referred ISO 7637-2 [42] is the only acceptable test method. The ICC method should be omitted while the test result will strongly depend on the undefined input impedance of the EUT and therefore cannot be claimed sufficiently reproducible for metrology purposes.

The test on battery voltage variations during cranking (table 40) as derived from ISO 16750-2 formerly made part of previous versions of ISO 7637-2 (pulse 4) which also accounts for the “load dump” test (former pulse 5). Please note that the latter may need to be implemented while certain regions (for example EU) yet require taking into account load dump transients.
Instrument performance tests (general)

9.1 Preliminary remarks

The brief descriptions of test procedures in this document are intended only for information. It will be necessary to consult the referenced IEC and ISO Publications before conducting a test.

Terminology used in the applicable IEC and ISO Publications was copied in this Document to the widest possible extent.

Some IEC and ISO Publications may use the term “specimen” instead of “EUT” as used in clause 10 - 14 of this Document. In this Document “specimen” concerns one copy of an instrument (or part of an instrument) and “EUT” concerns the specific copy on which the test is, or will be performed. So each of the instruments produced and being part of the population of the same type is called a “specimen” of the type. There might for example be a preference to perform examinations on a specimen different from the one used as EUT.

Most of the standards, referred to in the following chapters of this Document, concern “basic” standards (according to IEC definition) not specifically linked to a product. This implies that for many tests a choice may be made between more than one test levels. In order to optimize harmonization between those standards and the OIML Recommendations, all these test levels were copied from these standards into this Document, but only a limited number of these are actually recommended for implementing in OIML Recommendations. To be able to recognize the preferred test levels, these have been presented in bold face.

9.1.1. Measurement uncertainty considerations

Measurement uncertainty evaluation is an important and essential element in all aspects of metrology, including legal metrology. The (draft) OIML Guide on “The Role of Measurement Uncertainty in Conformity Assessment Decisions in Legal Metrology” should be consulted for a general understanding of the terminology and concepts related to uncertainty, and for guidance on how to assess and use measurement uncertainty.

Measurement uncertainty shall be considered in all aspects of measurement and conformity assessment decisions associated with OIML Recommendations. Some guidance on how to assess uncertainty is provided in the following paragraphs.

The following text should be included in all OIML Recommendations that are based on OIML D11:

“Each measurement result is subject to measurement uncertainty. Each test comprises measurements using harmonized test setups and verification of compliance with requirements. Every measurement result that is reported during testing of a measuring instrument or system within the framework of this Recommendation shall include the measured value along with its associated measurement uncertainty. Exceptions include those cases where individual measured values are obtained for the purpose of assessing a component of measurement uncertainty associated with the repeatability or reproducibility of the measuring instrument/system and/or testing procedure, or where it is determined on basis of a previous reported assessment that a component of measurement uncertainty is not significant in a particular measurement application.

The uncertainty of the test method shall be taken into account in the decision on the applicability of the test method.”

9.1.2. Evaluation of uncertainty in testing

The main argument for evaluation of the uncertainty of a test result is obtaining with sufficient high probability the assurance that a clear decision on compliance to the requirements can be made by taking into account this uncertainty on the result.

In the considerations on uncertainty in testing it is to be taken into account that a test is just an instant observation of the response of one or a few specimen(-s) on that test and sometimes for practical reasons even reduced to only a selection of the different manifestations of influencing phenomena. This may require extending uncertainty margins or the use of pooled uncertainty values for certain contributors.

In testing the procedure and set-up contribute to the overall uncertainty in the result and often even are the mayor contributors.

The contributors to the overall uncertainty in the test result comprise:
a) measuring instrumentation uncertainty  
b) test set up introduced uncertainty  
c) test procedure introduced uncertainty  
d) sample introduced uncertainty  

Examples of the above mentioned contributors are: (from temperature test and ESD test)  
a) thermometer in climate room; pulse waveform of ESD generator  
b) homogeneity of temperature in climate room; position of the EUT above a conducting cable  
c) curve of climate change; location for the discharge  
d) reproducibility of the measurements  

In Recommendations the overall uncertainty contribution may be stated a maximum acceptable value. Next to stating the overall contribution it may be required in Recommendations to set a maximum acceptable value to some specific uncertainty contributors in order to prevent an unnecessary increase of the overall uncertainty or in contrary unnecessary efforts in evaluation of the uncertainty of a contributor.  
The former referring, for example, to the situation where as reference a mass standard is used having a relatively high uncertainty, the latter referring for example to the situation where the actual uncertainty of the mass standards is calculated instead of the pooled uncertainty provided from its classification.  

Specific contributions to the (measurement) uncertainty  
a) may be obtained from calibration results of the reference instruments  
b) may be estimated on basis of the test method and procedure  
c) may be obtained from the reproducibility of test results  

Results of research during development or from evaluation of the test method and procedure shall provide the test method related contributions to the overall uncertainty.  

9.2 Test considerations  

9.2.1 General  
In principal, all tests shall be performed meeting the conditions concerning installation as stipulated by the manufacturer and the corresponding rated operating conditions unless it is obvious that these will not be relevant to the result of the test.  
The applicable OIML Recommendation shall in all cases describe the manner in which the instrument shall be tested as well as the allowed changes in the performance of the EUT. 
Simulation of any part of the EUT should be avoided. In case such simulation cannot be omitted all parts of the instrument that could be affected by the test shall play their intended role in the measurements. 
Many measuring instruments today contain electronic circuits and/or are equipped with electronic devices and therefore fulfill the definition of being an electronic measuring instrument. For these instruments the tests as referred to in sub-clause 8.4 apply. Measuring instruments which do not fulfill this definition need only be exposed to the mechanical and climatic tests as referred to in sub-clauses 8.2 and 8.3. 
In case the electronic measuring instrument only contains passive electronic components the test on influence quantities referred to in sub-clauses 8.4.6, 8.4.7, 8.4.8, 8.4.10 and 8.4.11 may not be applicable. 
Table 5 may serve as guideline showing the preferred method of evaluation of the test results in relation to the several tests presented in this Document (the applicable Recommendation may divert in evaluation method). 
Note: The value of specific influence quantities may in some cases exceed the rated operating conditions. Such a particular influence quantity is to be considered as an influence factor when its value lies within the rated operating conditions range and a disturbance when the value exceeds these rating operating conditions.

**Legend**

- **I**: Influence factor
- **D**: Disturbance
- **MPE**: Maximum permissible error according to 3.6
- **NSFa**: No significant fault shall occur after the disturbance.
- **NSFd**: No significant fault shall occur during the disturbance.
- (1): For integrating instruments
- (2): For non-integrating instruments
9.2.2 Integrating instruments
As a consequence of the operating principle of integrating instruments the evaluation approach has to be different from that of non-integrating instruments. This implies more attention to the evaluation sequence is needed and shall therefore be taken into account when prescribing tests and evaluation for such instruments. Examples of integrating instruments are: water, gas, electricity and heat meters as well as belt weighers. For evaluation of these instruments testing and observation over a certain established period of time of operation is needed.

9.2.2.1 Sequence during NSFa evaluation
The following test and evaluation sequence is recommended when NSFa evaluation is applicable:

(a) Establish the period of time needed per measurement
(b) Start measurements under reference conditions
(c) Stop the measurements after the period of time established and keep the EUT switched on. 1) 2)
(d) Determine the initial intrinsic error (Eii),
(e) Record all indicated and registered values of interest.
(f) Activate the disturbance generator,
(g) Record all indicated and registered values of interest. 3) The change in the display reading and registers may only alter by one unit or by the significant fault (to be prescribed in the relevant Recommendation),
(h) Perform a second measurement using the same period of time and
(i) Determine the intrinsic error (Ei),
(j) Calculate the fault being the difference between the intrinsic error and the initial intrinsic error. This fault shall not exceed the fault limit specified in the applicable Recommendation.

Notes:
1) In case of the damp heat – cyclic test the position “switched on” or “switched off” is to be specified in the Recommendation; the position “switched off” facilitates condensing.
2) Concerning step b, it may be possible that the test procedure prescribes the EUT being switched off (for instance the damp heat, cyclic test that has been classified as a disturbance).
3) Concerning step f, it may sometimes not be possible that the EUT after the application of the disturbance indicates the same result as it did before (in particular when needed to be switched off, or when the measurement range
does not allow an indication during performance of the test, which may for instance apply when performing mechanical shock tests on clinical thermometers).

9.2.2.2 Sequence during NSFd for evaluation

The following general test and evaluation sequence is recommended when NSFd evaluation is applicable:

a) Establish the period of time needed for a measurement
b) Start measurements under reference conditions
c) Stop the measurements after the period of time established and keep the EUTs switched on.\(^1\)\(^2\)
d) Determine the initial intrinsic error,
e) Apply the disturbance
f) Perform a second measurement
g) Stop applying the disturbance and
h) Determine the error,
i) Calculate the fault being the difference between the error in the second measurement and the initial intrinsic error. This fault shall not exceed the fault limit specified in the applicable Recommendation

For the test (damp heat, cyclic; table 9) the recommended sequence deviates from the general sequence as follows:

a) - e) according to the general test sequence
f) Start measurements 1 hour after the start of the increase of the temperature during the last cycle
g) Stop the measurement after the period of time established and keep the EUT switched on.\(^1\)\(^2\)
h) Determine the error,
i) After recovery perform a second measurement using the same period of time and
j) Determine the intrinsic error,
k) Calculate the fault being the difference between the error of indication in the second measurement and the initial intrinsic error. This fault shall not exceed the fault limit specified in the applicable Recommendation
l) Calculate the fault being the difference between the intrinsic error in the third measurement and the initial intrinsic error. This fault shall not exceed the fault limit specified in the applicable Recommendation.

g) electrical and mechanical measurements to be made at the end of the test, the parameters to be measured first, and the maximum period allowed for the measurement of these parameters

10.4 Atmospheric pressure

In table 11 and table 12, two tests for determining the influence of atmospheric influence on measuring instruments have been described. In general, it should be avoided to prescribe both tests in OIML Recommendations. Either of these tests shall only be prescribed in OIML Recommendations in those cases where, as a result of the physical principle of the measuring instruments, a significant influence of changes in atmospheric pressure can be expected (also refer to 4.4).

The choice on either the test and on the test level to be prescribed in the applicable Recommendation, is to be made by the responsible OIML Technical Committee or Subcommittee.

- **f)** the parameters to be measured first
- **g)** the maximum period allowed for the measurement of these parameters.

allowed for the measurement of these parameters
11 Mechanics related performance tests

11.1 Vibration

In table 15 and table 16, two vibration tests (random and sinus) have been described. In general, it should be avoided to require both tests in OIML Recommendations.

Implementation of the random vibration test is preferred in OIML Recommendations.
The sinusoidal vibration test shall be applied only in those cases where the measuring instrument is expected to be typically subjected to sinusoidal vibrations.

Selection guidance on both tests can be found in IEC 60068-3-8 [16]

<td>Exposure to electrostatic discharge (ESD)</td>
</tr>
<tr>
<td>Applicability</td>
<td>Applicable to all electronic measuring instruments</td>
</tr>
<tr>
<td>Object of the test</td>
<td>Verification of compliance with the provisions in 5.1.1 or 5.1.2 in case of direct exposure to electrostatic discharges or such discharges in the neighbourhood of the EUT</td>
</tr>
<tr>
<td>Test procedure in brief</td>
<td>The test comprises exposure of the EUT to electrical discharges. An ESD generator as defined in the referred standard shall be used and the test set-up shall comply the dimensions, materials used and conditions as specified in the referred standard. Before starting the tests, the performance of the generator shall be verified. At least 10 discharges per preselected discharge location shall be applied. The time interval between successive discharges shall be at least 1 second. For EUT not equipped with a ground terminal, the EUT shall be fully discharged between discharges. If the EUT is an integrating instrument, the test pulses shall be applied continuously during the measurement time. Contact discharge is the preferred test method. Air discharge is far less defined and reproducible and therefore shall be used only where contact discharge cannot be applied. Direct application: In the contact discharge mode to be carried out on conductive surfaces, the electrode shall be in contact with the EUT before activation of the discharge. In such case the discharge spark occurs in the vacuum relays of the contact discharge tip. On insulated surfaces only the air discharge mode can be applied. The EUT is approached by the charged electrode until a spark discharge occurs. Indirect application: The discharges are applied in the contact mode only on coupling planes mounted in the vicinity of the EUT.</td>
</tr>

</tr>
<tr>
<td>Object of the test</td>
<td>Verification of compliance with the provisions in 5.1.1 or 5.1.2 during low battery voltage</td>
</tr>
</tbody>
</table>
| Test procedure | The test comprises exposure of the EUT to the specific low battery level condition during a period sufficient for achieving temperature stability and for performing the required measurements. The maximum internal impedance of the battery and the minimum battery supply voltage level ($U_{b_{min}}$) are to be specified by the manufacturer of the instrument. In case of simulating the battery by using an alternative power supply source like in bench testing, the internal impedance of the specified type of battery shall also to be simulated. The alternative power supply shall be capable to deliver sufficient current at the applicable supply voltage.
   
   The test sequence is as follows:
   
   - Let the power supply stabilize at a voltage as defined within the rated operating conditions and apply the measurement and/or loading condition.
   - Record:
     a) the data defining the actual measurement conditions including date, time and environmental conditions,
     b) the actual power supply voltage.
   - Perform measurements and record the error (-s) and other relevant performance parameters.
   - Verify compliance with clauses 5.1.1 and 5.1.2
   - Repeat the above procedure with actual supply voltage at $U_{b_{min}}$ and again at 0.9 $U_{b_{min}}$
   
   Verify compliance with the requirements stated in the sub clauses of 5.5. |
| Test level index | 1 |
| Lower limit of the voltage | The lowest voltage at which the EUT functions properly according to the specifications |
| Number of test cycles | At least one test cycle for each functional mode |
| Information to be presented in the applicable recommendation, where relevant | a) preconditioning of the EUT  
 b) measurements and/or loading during conditioning and test  
 c) number of test cycles  
 d) maximum allowable variations  
 e) response of the EUT to low supply voltage; for instance indication or switch off |
14.2 Power from external 12V and 24 V road vehicle batteries

Note:
The nominal voltage $U_{\text{nom}}$ of the electrical system in road vehicles is usually 12 V or 24 V. But the practical voltage at the battery-terminals of a road vehicle can vary considerably. ISO 7637-2 [42], specifies reference levels of 13.5 V and 27 V respectively.

It is likely that the future will bring 42 V systems too, but these are not yet included in the ISO 7637-series of standards, nor in ISO 16750-2 [40]. Therefore, no attempt is made to include them in this version of OIML D 11.

Notes: (1) In ISO 7637-2 [42], so called “test levels”.

(2) In ISO 7637-2 [42], the former levels I and II were deleted because concerning transients in road vehicles these do not ensure a sufficient level of immunity.

(3) The text of this standard indicates that this standard is primarily intended as a basis for contracts between manufacturers of motor vehicles and electronic sub-assemblies. As instruments shall comply with the provisions in 5.1.1 or 5.1.2 in any type of car, test level IV is advised to incorporate in OIML Recommendations.

(4) Test pulses 1, mentioned in the standard is considered not applicable. Former test pulses 4 and 5 are no longer covered by the recent ISO 7637-2. Instead the recent ISO 16750-2 covers the phenomenon of energizing starter motor circuits of combustion engines. Refer Table 40.

(5) Test pulse 2b is only applicable in case the measuring instrument may be connected to the battery via the main switch of the car, so if the manufacturer of the measuring instrument has not specified that the instrument is to be connected directly to the battery.

Information to be presented in the applicable Recommendation, where relevant:

a) test pulses to be applied
b) test level to be applied
c) minimum number of pulses or test time
d) performance of the EUT during and after the test pulses

- e) performance of the EUT during and after the test pulse
ANNEX A

Documentation for type evaluation

(Informative)

The applicable Recommendation specifies the documentation to be submitted with the application for type approval which at least includes information concerning the:

- principle of operation
- actual design
- integrity securing measures
- software and data management
- installation requirements
- operating instructions
- provisions for testing, servicing and maintenance
- specific instrument or device depending measures needed
- evidence on compliance to the requirements of the Recommendation

Examples:

centering the principle of operation
- specific description/flowchart giving the technical characteristics and the principle of operation

centering the actual design
- design drawings; photographs; panel layout;
- flow diagram of the logic, showing the functions of the constituent devices;
- description of the devices with drawings, diagrams
- lists of the essential constituent devices, modules and components with their essential characteristics;

centering the integrity securing measures
- installation and security sealing plan,
- drawing(s) presenting the security sealing plan and the provisions and location for verification marks;
- drawing of regulatory markings;

centering software and data management
- specific information on the software required
- assessment of metrological relevant software [and revision number of software].

centering the installation requirements
- an assembly drawing with identification of different constituent parts;
- installation practices or operational constraints;

centering operating instructions
- user and installer manual
- for correction devices, a description of the determination and execution of the correction;

centering
- for switching to a test service or maintenance mode

centering specific instruments and assemblies
- a list of the parts being of influence to the metrological behaviour with a description of their constituent materials

centering evidence on compliance to the requirements of the Recommendation
- (part-)certificates and test reports
- declaration of conformity by the manufacturer
ANNEX B
DURABILITY ASSESSMENT
(Informative)

B.1 Introduction

B.1.1 Objective

The objective of durability assessment is to verify the instruments’ capability to operate correctly within the performance criteria over the required period of time. Since deterioration of an instrument may occur (i) due to the failure of one of its components, which may happen at an unpredictable moment during its lifetime, or (ii) due to the gradually wear and tear the durability assessment comprises determination of the capability of the instrument to:

- act adequately upon the failure of a component;
- collect information on the possible occurrence of defects during its complete lifetime.

B.1.2 Verification of the instrument capability to act adequately upon failure of a part or component

Tests may be carried out to verify the correct performance of durability protection facilities and checking facilities by creating situations where these facilities meant to act upon, provided that the integrity of the instrument is maintained. Study of the documentation on circuitry may give guidance. The applicable Recommendation may specify the parts that are to be tested. Special attention should be paid to parts (electronic or mechanic) which may be expected to gradually change in properties during the lifetime of the instrument.

B.1.3 Assessment of the possible occurrence of defects during the lifetime of the complete measuring system

Information concerning this subject can only be collected by performance of an actual endurance tests simulating the complete lifetime by accelerating in time the instruments’ wear and tear. The manufacturer may have carried out such tests in order to ameliorate the overall quality of the instrument by reinforcing certain parts, to elaborate other solutions for certain problems, or to set up an adequate maintenance system.

It is recommended that the testing authority requests documentation concerning these tests. The applicable Recommendation may specify certain endurance tests.

B.2 Characteristics of durability protection

Durability protection in its basic form provides the operator with information concerning the status of the instrument. He may be warned that a certain operation time has elapsed or that the instrument itself has detected a significant durability error and is consequently invited to take corrective actions; alternatively, he may be recommended to carry out certain checking operations.

A proper intake for protection may be the time factor itself, in which case an obvious moment for checking operations is the switching-on of the instrument, or for example the switching on of a display or an additional device. Another approach may be the use of timers or operation cycle counters, which would determine other checking times based on the known or estimated frequency of the occurrence of durability errors.

In these cases, the operator may be given a certain lapse of time to carry out his checking operations at a suitable moment; after that time, however, the instrument shall discontinue its operation if the checks have not been done.

In more sophisticated forms of durability protection, the instrument may automatically compare the result of checking operations with stored result values and automatically conclude whether it is still in good condition or not. If the self-checking involves the application of physical reference standards (for example in weighing instruments) monitoring of the durability of analogue input transducers will also be possible.

Within the instrument, the circuits warranting durability protection shall represent a logical function with self-checking properties. Since significant durability errors normally need a certain time interval to develop, this self-checking action may be intermittent, and very often an interlock with the switch-on procedure may be sufficient.

Durability protection should not be confused with protection against disturbances and influence factors, although checking facilities sometimes also monitor durability aspects, for example by detecting a significant fault that occurs due to the wearing of a component in the measuring chain. The objective of both requirements 5.1.2 and 5.1.3 is to safeguard the routine measurement operations of the instrument against failures.

The applicable Recommendation may contain prescriptions concerning the means for securing digital signal handling in the case of a self-checking ability. The difference in self-checking frequency (automatic and permanent for some
routine operations; intermittent for durability effects) is to be seen as a consequence of speed: a slow evolution of durability errors opposed to the transmission of typically one million information-carrying pulses every second in the digital signal processing.

Where transmission and storage of digital data has been sufficiently protected, the internal function of a typical microprocessor (which processes program instructions as well as arithmetical operations through the same function blocks) may be considered as self-checked by its normal operation.
ANNEX C

FACILITY FOR TESTS ON BAROMETRIC PRESSURE

(Informative)

C.1 Introduction

At publication date of this document no publication is available on a standard method describing a test facility for the evaluation of the influence of minor changes in the barometric pressure on the performance of measuring instruments. As the performance of certain measuring instruments can be influenced by changes in atmospheric pressure, exposing these to such test makes sense. Typical example is the influence on the zero-output of certain designs of load cells, having a low excitation voltage.

This Annex presents a brief description for a simple test set-up, primarily designed and designated for testing load cells, but also applicable for other relatively small EUTs with a safe low excitation voltage.

For this test, it should be emphasized that the changes in pressure introduced are very small: the difference in atmospheric pressure between the test chamber and the outer atmosphere will never exceed 20 kPa. So no special precautions need to be taken with respect to pressure related safety measures.

Furthermore, there is no need to control the exact pressure; it will be sufficient to control the difference between the pressure in the pressure chamber and the atmospheric pressure in the laboratory.

When using a small pressure-chamber for the testing of electronic measuring instruments a practical problem is making the connection for the cable(s) between the pressure-room and the outer atmosphere airtight using simple means and without a need to dismantle the connection plug(s).

C.2 Facility for barometric pressure test

It must be clearly emphasized that the facility described below is just one possible solution. Other solutions may be equally acceptable.

In the described facility, the problem of getting an airtight feed-through for the cables is solved by creating a water-slot and using it to generate the changes in pressure as well.

The principle of the test facility is depicted in Figure 1 and a practical set-up is shown in Figure 2.

The vessel (1) is partly filled with water.

The EUT (2) is placed on a table (3) and prevents the EUT getting wet.

A transparent vessel (4), having a smaller diameter than the one mentioned before, is placed upside down within the first vessel (1) to form a water seal (5) between the two vessels. Furthermore, there should be a means (6) that prevents the vessel from floating. This could be either a bar like shown in Figure 2 or some heavy object.

The pressure above the water level in the second vessel (7) can be set by means of a manually operated pump (8) and its level read on a pressure gauge (9).

The water seal (5) between the two vessels solves the problem of an airtight feed-through for the cables.

The vessel (1) shown in Figure 2 a has a diameter of about 50 cm.

The pressure in the chamber can be increased by either a small hand-pump or by adding a small amount of water.

As an alternative for the pressure gauge (9), a water manometer (10) consisting of a water-filled plastic tube and a ruler could be used.

Warning:

Due to the presence of water and a metal housing, this facility can only be of use for situations were only safe low voltages occur, or no electric power at all.
Figure B-1 The basic principle

Figure B-2 The practical set-up
ANNEX D
BIBLIOGRAPHY and NOTES

At the time of Publication, the editions indicated were valid. All normative documents are subject to revision, and the users of this Document are encouraged to investigate the possibility of applying the most recent editions of the normative documents indicated below. Members of IEC and ISO maintain registers of currently valid International Standards.

The actual status of the standards referred to can also be found on the Internet:
IEC Publications: http://www.iec.ch/searchpub/cur_fut.htm
OIML Publications: http://www.oiml.org/publications/ (with free download option of PDF files)

In order to prevent any misunderstanding, it is highly recommended that all references to standards in OIML Recommendations and International Documents shall be followed by the version referred to (mostly year or date).

<td>IEC 60068-2-18 Ed. 2.0 (2000-10) Environmental testing - Part 2-18: Tests - Test R and guidance: Water</td>
<td>Provides methods of test applicable to products which, during transportation, storage or in service, may be subjected to falling drops, impacting water or immersion. The primary purpose of water tests is to verify the ability of enclosures covers and seals to maintain components and equipment in good working order after and, when necessary, under a standardized drop field or immersion in water. These tests are not corrosion tests and should not be considered and used as such. The effects of a large temperature difference between the water and the specimen, such as increased water ingress resulting from pressure changes, as well as thermal shock, are not simulated. Established water tests in other standards are not intended to simulate natural rainfall and their quoted intensities are too high to be adopted for that purpose. Therefore, in addition to the high-intensity severities, Test R includes an artificial rain test based upon natural conditions but not taking into account high wind speeds generally associated with natural rain. Guidance is given on the applicability of the tests and the severities to be selected.</td>

</tbody>
</table>
| [13] | IEC 60068-2-78 Ed. 1.0 (2001-08) Environmental testing - Part 2-78: Tests - Test Cab: Damp heat, steady state | (IEC 60068-2-78 replaces the following withdrawn standards: IEC 60068-2-3, test Ca and IEC 60068-2-56, test Cb) | Provides a test method for determining the suitability of electro technical products, components or equipment for transportation, storage and use under conditions of high humidity. The test is primarily intended to permit the observation of the effect of high humidity at constant temperature without condensation on the specimen over a prescribed period. This test provides a number of preferred severities of high temperature, high humidity and test duration. The test can be applied to both heat-
dissipating and non-heat dissipating specimens. The test is applicable to small equipment or components as well as large equipment having complex interconnections with test equipment external to the chamber, requiring a set-up time which prevents the use of preheating and the maintenance of specified conditions during the installation period.

[14] IEC 60068-3-1 Ed. 1.0 (1974-01) + Supplement A (1978-01) Environmental testing Part 3-1: Background information,- Cold and dry heat tests

Gives background information for Tests A: Cold (IEC 68-2-1), and Tests B: Dry heat (IEC 68-2-2). Includes appendices on the effect of: chamber size on the surface temperature of a specimen when no forced air circulation is used; airflow on chamber conditions and on surface temperatures of test specimens; wire termination dimensions and material on surface temperature of a component; measurements of temperature, air velocity and emission coefficient. Supplement A gives additional information for cases where temperature stability is not achieved during the test.

[15] IEC 60068-3-4 Ed. 1.0 (2001-08) Environmental testing - Part 3-4: Supporting documentation and guidance - Damp heat tests

Provides the necessary information to assist in preparing relevant specifications, such as standards for components or equipment, in order to select appropriate tests and test severities for specific products and, in some cases, specific types of application. The object of damp heat tests is to determine the ability of products to withstand the stresses occurring in a high relative humidity environment, with or without condensation, and with special regard to variations of electrical and mechanical characteristics. Damp heat tests may also be utilized to check the resistance of a specimen to some forms of corrosion attack.

[16] IEC 60068-3-8 Ed. 1.0 (2003-08) Environmental testing - Part 3-8: Supporting documentation and guidance - Selecting amongst vibration tests

Provides guidance for selecting amongst the IEC 60068-2 stationary vibration test methods Fc sinusoidal, Fh random and F(x) Mixed mode vibration. The different steady-state test methods and their aims are briefly described in Clause 4. Transient test methods are not included. For vibration testing, the environmental conditions, especially the dynamic conditions for the specimen, should be known. This standard helps to collect information about the environmental conditions (Clause 5), to estimate or measure the dynamic conditions (Clause 6) and gives examples to enable decisions to be made on the most applicable environmental vibration test method. Starting from the condition, the method of selecting the appropriate test is given. Since real life vibration conditions are dominated by vibration of a random nature, random testing should be the commonly used method, see Table 1, Clause 7. The methods included hereafter may be used to examine the vibration response of a specimen under test before, during and after vibration testing. The selection for the appropriate excitation method is described in Clause 8 and tabulated in Table 2. In this standard specification, writers will find information concerning vibration test methods and guidance for their selection.

Defines a standard test method to assess the ability of a connector to withstand driving fine sand and dust.

[18] IEC 60512-14-7 Ed. 1.0 (1997-10) Defines a standard test method to assess the effects of

<td>IEC 60529 Ed. 2.1 (2001-02) Degrees of protection provided by enclosures (IP Code) Corr.1 (2003-01) Ed. 2.1 Corr.2 (2007-10) Ed. 2.1</td>
<td>Applies to the classification of degrees of protection provided by enclosures for electrical equipment with a rated voltage not exceeding 72.5 kV.</td>
</tr>
<tr>
<td>IEC 60654-2 Ed. 1.0 (1979-01), with amendment 1 (1992-09) on Ed. 1.0 Operating conditions for industrial-process measurement and control equipment Part 2: Power</td>
<td>Gives the limiting values for power received by land-based and offshore industrial-process measurement and control systems or parts of systems during operation. Maintenance and repair conditions are not considered</td>
</tr>
<tr>
<td>IEC 60721-2-5 Ed. 1.0 (1991-07) Classification of environmental conditions - Part 2-5: Environmental conditions appearing in nature - Dust, sand, salt mist</td>
<td>Presents characteristics of dust, sand and salt mist appearing in nature, and describes the influences from these environmental factors to which products are liable to be exposed during storage, transportation and use.</td>
</tr>
<tr>
<td>IEC 60721-3-3 Consolidated Ed. 2.2 (2002-10) with correction1 (2008-06) on Ed. 2.2 Part 3-3: Classification of groups of environmental parameters and their severities - Stationary use at weather-protected locations</td>
<td>Classifies groups of environmental parameters and their severities to which products are subjected when mounted for stationary use at weather-protected locations.</td>
</tr>
<tr>
<td>IEC 60721-3-4 Ed. 2.0 (1995-01) with Amendment 1 (1996-11) Part 3-4: Classification of groups of environmental parameters and their severities - Stationary use at non-weather protected locations.</td>
<td>Classifies groups of environmental parameters and the severities to which a product may be exposed under use conditions, including periods of erection work, downtime, maintenance and repair, when mounted for stationary use at locations which are non-weather protected.</td>
</tr>
<tr>
<td>IEC/TR 61000-2-1 Ed. 1.0 (1990-05) Electromagnetic compatibility (EMC) Part 2: Environment Section 1: Description of the environment - Electromagnetic environment for low-frequency conducted disturbances and signalling in public power supply systems</td>
<td>Has the status of a technical report, and gives information on the various types of disturbances that can be expected on public power supply systems. The following disturbance phenomena are considered: - harmonics - inter-harmonics - voltage fluctuations - voltage dips and short supply interruptions - voltage unbalance - mains signalling - power frequency variation - DC components</td>
</tr>
<tr>
<td>IEC 61000-2-2 Ed. 2.0 (2002-03) Electromagnetic compatibility (EMC) Part 2 Environment Section 2: Compatibility levels for low-frequency conducted disturbances and signalling in public low-voltage power supply systems</td>
<td>This standard is concerned with conducted disturbances in the frequency range from 0 kHz to 9 kHz, with an extension up to 148.5 kHz specifically for mains signalling systems. It gives compatibility levels for public low voltage AC distribution systems having a nominal voltage up to 420 V, single-phase or 690 V, three-phase and a nominal frequency of 50 Hz or 60 Hz. Compatibility levels are specified for electromagnetic disturbances of the types which can be expected in public low voltage power supply systems, for guidance in: - the limits to be set for disturbance emission into public power supply systems; - the immunity limits to be set by product committees and others for the equipment exposed to the conducted disturbances present in public power supply systems.</td>

<td>[26] IEC/TR 61000-2-5 Ed.2.0 (2011-05) Electromagnetic compatibility (EMC) – Part 2: Environment; Section 5 Description and classification of electromagnetic environments.</td>
<td>This publication is a technical report intended for guidance for those who are in charge of writing immunity standards for an equipment or system. Its purpose is to classify electromagnetic environments and help improve the specification of the immunity requirements of an item containing electrical or electronic parts, and consequently obtain electromagnetic compatibility. It also gives basic guidance for the selection of immunity levels. The data are applicable to any equipment, subsystem or system making use of electromagnetic energy and operating in a specific location as defined by this report.</td>

<td>[27] IEC 61000-4-1 Ed.3.0 (2006-10) Basic EMC Publication Electromagnetic compatibility (EMC) Part 4: Testing and measurement techniques Section 1: Overview of IEC 61000-4 series</td>
<td>Provides applicability assistance to the users and manufacturers of electrical and electronic equipment on EMC standards within the IEC 61000-4 series on testing and measurement techniques. Provides general recommendations concerning the choice of relevant tests.</td>
</tr>
<tr>
<td>[28] IEC 61000-4-2 Ed. 2.0 (2008-12) Basic EMC Publication Electromagnetic compatibility (EMC) Part 4: Testing and measurement techniques Section 2: Electrostatic discharge immunity test</td>
<td>Provides the immunity requirements and test methods for electrical and electronic equipment subjected to static electricity discharges, from operators directly, and from any person to adjacent objects. It additionally defines ranges of test levels which relate to different environmental and installation conditions and establishes test procedures.</td>
</tr>
<tr>
<td>[29] IEC 61000-4-3 consolidated Ed. 3.1 (2008-04) Basic EMC Publication ISH-1 (2008-08) (Interpretation sheet 1) to Ed. 3.1 Electromagnetic compatibility (EMC) Part 4: Testing and measurement techniques Section 3: Radiated, radio-frequency, electromagnetic field immunity test</td>
<td>Provides the immunity requirements of electrical and electronic equipment to radiated electromagnetic energy. It establishes test levels and the required test procedures. Establishes a common reference for evaluating the performance of electrical and electronic equipment when subjected to radio-frequency electromagnetic fields.</td>
</tr>
<tr>
<td>[30] IEC 61000-4-4 Ed. 2.0 (2004-07) and correction 1 on Ed. 2.0 (2006-08) correction 2 on Ed. 2.0 (2007-06) and amendment1 to Ed. 2.0 (2010-01) Electromagnetic compatibility (EMC) Part 4: Testing and measurement techniques Section 4: Electrical fast transient/burst immunity test</td>
<td>Establishes a common and reproducible reference for evaluating the immunity of electrical and electronic equipment when subjected to electrical fast transient/bursts on supply, signal, control and earth ports. The test method documented in this part of IEC 61000-4 describes a consistent method to assess the immunity of an equipment or system against a defined phenomenon. The standard defines: - test voltage waveform; - range of test levels; - test equipment; - verification procedures of test equipment; - test set-up; - test procedure. The standard gives specifications for laboratory and post-installation tests.</td>

<td>Provides the immunity requirements, test methods, and range of recommended test levels for electrical and electronic equipment to unidirectional surges caused by overvoltages from switching and lightning transients. Several test levels are defined which relate to different environment and installation conditions. It establishes a common reference for evaluating the performance of equipment when subjected to high-energy disturbances on the power and inter-connection lines.</td>
